Sensitive Habitat: In El Dorado County, this includes the following habitat types: montane riparian, valley-foothill riparian, aspen, valley oak woodland, wet meadow, and vernal pools (General Plan EIR).

Tree Survey, Preservation, and Replacement Plan: A plan that identifies trees at the project site, shows how specific trees shall be protected during development and related work, and includes any required mitigation measures and ensures viability of trees after construction. A Tree Survey, Preservation, and Replacement Plan is a stand-alone report, and is also included as part of an Important Habitat Mitigation Program. The plan shall be prepared by a qualified professional. See separate guidelines for requirements.

Woodland Habitats: Biological communities that range in structure from open savannah to dense forest. In El Dorado County, major woodland habitats include blue oak-foothill pine, blue oak woodland, montane hardwood, montane hardwood-conifer, and montane riparian.

Guidance for Application of Policy 7.4.4.4:

1. Trees subject to canopy retention and replacement – Policy 7.4.4.4 is intended to apply exclusively to retention and replacement of oak canopy within oak woodlands. All oak trees, of all sizes, are included in the measurement of oak canopy.

Any oak tree canopy, landmark or heritage trees, including native oak trees that do not qualify for review as oak woodland under Policy 7.4.4.4 may be subject to review under Policy 7.4.5.2.
2. Minimum oak canopy area – The oak canopy retention requirements of Policy 7.4.4.4 are intended only to apply to:
 - a. Parcels greater than 1.0 acre that contain 1 percent or more oak canopy cover; or
 - b. Parcels 1.0 acre or smaller that contain 10 percent or more oak canopy cover.
3. Exceptions to oak canopy retention/replacement requirements – Policy 7.4.4.4 intends that the following activities are not subject to oak canopy cover retention or replacement requirements:

- a. Agricultural cultivation/operations, whether for personal or commercial purposes, on land planned (AL, NR, RR, and Agricultural Districts [-A]) or zoned (AE, AP, A, PA, SA-10, RA, TPZ, and MR) for agricultural use per Policy 2.2.1.5 (Table 2-4 General Plan Land Use Designation and Zoning District Consistency Matrix, page 21), by the El Dorado County General Plan or Zoning Ordinance;
- b. Tree removal associated with an approved Fire Safe Plan as necessary to protect an existing structure or structures. The Fire Safe Plan shall take into consideration the El Dorado County Department of Forestry SRA Fire Safe Regulations and the CDF General Guidelines for Creating Defensible Space. Fire Safe Plans are prepared by a RPF or other qualified professional subject to review and approval by the County. See Exhibit One for more information.
- c. Development on parcels that are one acre or larger and have less than 1 percent total oak canopy cover;
- d. Development on parcels that are less than one acre and have less than 10 percent total oak canopy cover; or
- e. Oak trees determined to be dead or diseased and dying by a certified arborist or registered forester are excluded from calculations of canopy cover and retention and replacement requirements.
- f. Applicant has “self certified” compliance with Policy 7.1.2.2. For properties located outside of an Important Biological Corridor (IBC) and Mitigation Area 0 of the Ecological Preserve (EP), the removal of natural vegetation, including oak trees (less than 36 inches dbh), is demonstrated to be limited to areas proposed to be graded or cleared for single-family residential development to include the following (for ministerial permits and Director approved design review applications):
 - Primary residence
 - Accessory structures (including secondary residence, garages, workshops, barns, swimming pools, decks, etc.)
 - Driveways and parking area
 - Septic systems
 - Wells and storage tanks
 - Propane tanks

- Yard areas immediately surrounding the primary residence and any accessory structure
- Yard areas immediately surrounding the primary and any accessory structures
- Retaining walls necessary for any of the above

Replacement of oak trees will be required on-site to the greatest extent feasible and an oak replacement agreement shall be recorded requiring self-monitoring and maintenance.

4. Qualified Professional – For the purposes of Policy 7.4.4.4, “Qualified Professionals”, refers to professionals approved by Development Services, suitably trained and experienced in wildlife biology, botany, arboriculture, or forestry such as qualified wildlife biologists, I.S.A. certified arborists, or Registered Professional Foresters (RPFs) can determine “habitat” value and canopy cover of oak woodlands determined from baseline aerial photography. The professional may be under contract to either the County or the property owner. The professional should be able to perform a species-focused site survey, use GPS to locate species and habitat on a map or aerial photograph, and should be able to address oak tree corridors (if applicable) for Policy 7.4.4.5. The qualified professional will need to prepare a Biological Resources Study and Important Habitat Mitigation Program that satisfies County requirements. In the event that a dispute arises involving the contents of the Biological Resources Study and/or Important Habitat Mitigation Program the County may refer the matter to an outside qualified consultant, retained by the County and paid for by the applicant/property owner, to develop recommendations for dispute resolution.

If there is a need to provide a survey level of detail to fully ascertain which canopy level applies per Policy 7.4.4.4, then the survey shall be conducted by a California professional engineer or a California professional land surveyor.

Generalized maps may be provided by a qualified professional using GPS.

5. Site Assessment Form and Tree Survey, Preservation, and Replacement Plan Required: An initial Site Assessment Form (Attachment 1) and Tree Survey, Preservation, and Replacement Plan must be prepared by a qualified professional and submitted to the Planning Services Division for review for all projects proposing removal of oak canopy cover. The purpose of the Site Assessment is to determine if the proposed removal of oak canopy cover would impact any of the following:

- Landmark or heritage trees (See Policy 7.4.5.2 A);

- Oak corridor continuity, between all portions of existing stands of oak woodland habitat with connecting corridors at a tree density that is equal to the density of the stand (See Policy 7.4.4.5);
- Sensitive or important oak woodland habitats (See Policy 7.4.5.2 A);
- Oak woodland within or directly adjacent to an important biological resource corridor overlay or an ecological preserve overlay (See Policies 7.4.2.9 and 7.4.1.4);
- Listed or special status plant or animal species observed or expected to occur on the project site or in adjacent areas that may be directly or indirectly affected by the project (See Policy 7.4.1.5); or
- Removal of oak canopy that exceeds retention requirements of Policy 7.4.4.4.

For discretionary projects, the Site Assessment must also include a conclusion by the qualified professional as to whether the proposed oak tree canopy cover removal would have the potential to cause a significant effect on the environment.

If the Site Assessment concludes that the project would not impact any of the above, and the County concurs, and the retention/replacement requirements of Policy 7.4.4.4 are satisfied, the proposed oak tree canopy cover removal may be found consistent with Policy 7.4.4.4 without preparation of a Biological Resource Study and Important Habitat Mitigation Program. A Tree Survey, Preservation, and Replacement Plan, prepared according to County requirements, shall be required prior to issuance of a grading or building permit for the project. The Tree Survey, Preservation, and Replacement Plan will address long term preservation as well as protection of oak trees required to be retained or replaced during grading and construction.

If the Site Assessment, or the County, concludes that the proposed project would impact any of the above resources, and/or for discretionary projects could have the potential to cause a significant impact on the environment, then a full Biological Resources Study and Important Habitat Mitigation Program for the project must be provided to the County for review and approval. For ministerial projects, this must occur prior to issuance of a grading or building permit for the project. For discretionary projects, this must occur as part of the environmental review process. The recommendations of the plan must be fully implemented prior to final grading or building inspection for the project.

6. Project Sites Within or Directly Adjacent to Important Biological Corridor Overlay or Ecological Preserve Overlay Areas: Any projects (ministerial or discretionary) proposing any oak canopy cover removal within or directly

~~adjacent to the~~ an Important Biological Corridor Overlay Designation or Ecological Preserve Overlay Designation shall require the submittal of Oak/Canopy Site Assessment Form, tree survey, and biological report. Should a dispute arise regarding recommendations of the biological report, review by the Planning Commission will be required to ensure consistency with Policies 7.4.2.9 and 7.4.1.4 unless the subject property is also located within an Agricultural District Overlay or Agricultural Lands designation in which case it would not be subject to additional requirements per Policy 7.4.2.9. The Biological Resources Study and Important Habitat Mitigation Program must address the requirements of Policies 7.4.2.9 and 7.4.1.4, including, but not limited to the potential for higher oak canopy cover retention and mitigation standards than for projects located outside of the Important Biological Corridor Overlay and Ecological Preserve Overlay areas.

7. Replacement Provisions – Where Policy 7.4.4.4 requires oak canopy cover replacement, the replacement shall be at a 1:1 ratio of canopy removed to canopy replaced as defined in these Guidelines or as specified by a qualified professional approved by the County. The 1:1 replacement ratio can be determined by a simple projection of an aerial photograph justified to the same scale as the underlying parcel is sufficient to estimate the land area, measured in square feet, subject to oak canopy coverage (land area in square feet shall be converted to acreage). Replacement may be by one of the following methods, at the discretion of the Development Services Director (Director):
 - a. On-Site Replacement Tree Planting. The replacement requirement is calculated as set forth in the tree replacement formula. Refer to the 1:1 Woodland Replacement definition. Replacement trees are to be planted on-site to the satisfaction of the Development Services Director. The size of the designated replacement area shall equal at a minimum the total area of the oak canopy cover proposed to be removed. An agreement to the satisfaction of County Counsel and the Director shall be required to ensure the long term maintenance and preservation of any on or off-site replacement trees planted. Maintenance and monitoring shall be required for a minimum of 10 years after planting. Any trees that do not survive during this period of time shall be replaced by the property owner.
 - b. On-Site Planting of Acorns. Under the direction of a qualified biologist, certified arborist and/or registered professional forester, acorns may be planted at a density designed to achieve oak canopy coverage which will equal the canopy coverage removed within no more than 15 years from the date of planting. The

minimum replacement ratio for acorns is calculated as set forth in the tree replacement formula. Refer to the 1:1 Woodland Replacement definition. Recommendations from the qualified professional shall include a minimum of: site planting design; acorn planting ratios to ensure success; acorn collection areas or nurseries; propagation measures; acorn protection techniques; maintenance, and monitoring and reporting. The size of the designated replacement area shall equal at a minimum, the total area of the oak canopy cover that is proposed to be removed. An agreement to the satisfaction of County Counsel and the Director shall be required to ensure the long term maintenance and preservation of any on or off-site replacement acorns planted. Maintenance and monitoring shall be required for a minimum of 15 years after planting. Any trees that do not survive during this period of time shall be replaced by the property owner.

- c. On-Site Replacement of Canopy Area. Under the direction of a qualified biologist, certified arborist and/or registered professional forester, acorns, oak trees or a combination of both may be planted on-site. The replacement requirement is calculated as set forth in the tree replacement formula. Refer to the 1:1 Woodland Replacement definition. Replacement plantings should be at a density designed to achieve oak woodland canopy coverage which will equal the canopy coverage removed within 15 years from date of planting or sooner.

Recommendations from the qualified professional shall include a minimum of: Site planting design; planting ratios to ensure success; any required acorn collection areas or nurseries; propagation measures; acorn and tree protection techniques; maintenance, monitoring and reporting requirements. The size of the designated replacement area shall equal at a minimum, the total area of the oak canopy cover that is proposed to be removed. An agreement to the satisfaction of County Counsel and the Director shall be required to ensure the long term maintenance and preservation of any replacement trees and/or acorns planted. Maintenance and monitoring shall be required for a minimum of 10 years after planting. Any trees that do not survive during this period of time shall be replaced by the property owner.

Replacement (and execution of related maintenance and monitoring agreements) shall be completed to the County's satisfaction prior to final grading or building inspection of the project.

- d. Off-Site Replacement of Canopy Area. The applicant may be permitted to procure an off-site planting area for the replacement trees and/or planting of acorns, preferably in close proximity and/or in connection with any oak woodland contiguous to the project site or within or adjacent to an Important Biological Corridor or Ecological Preserve as designated in the General Plan, to implement the replacement planting. The size of the off-site replacement planting area shall equal at a minimum the total area of oak canopy cover proposed to be removed. Oaks planted shall have characteristics of the receiver site. Replacement shall occur at a 1:1 ratio as defined in these Guidelines or as otherwise specified by a qualified professional approved by the County. A Conservation Easement to the satisfaction of County Counsel and the Director shall be required to ensure the long term maintenance and preservation of any on or off-site replacement trees and/or acorns planted. The Conservation Easement shall provide for the preservation of the designated area in perpetuity and shall include such terms, conditions, and financial endowments for monitoring and management deemed necessary by the County to ensure the long term preservation of the oak woodland within the easement area. The Conservation Easement shall be in favor of the County or a County approved conservation organization. Maintenance and monitoring shall be required for a minimum of 10 years (15 years for acorns) after planting. Any trees that do not survive during this period of time shall be replaced by the property owner; or
- e. Off-Site Conservation Easement to Protect Existing Oak Woodland in Lieu of Replacement. The applicant may obtain a Conservation Easement on property off-site with healthy oak woodland canopy area equivalent to 100 percent of the oak canopy area proposed to be removed. The conservation easement site should either be in close proximity and/or in connection with any oak woodland contiguous to the project site or within or adjacent to an Important Biological Corridor or Ecological Preserve as designated in the General Plan. The Conservation Easement shall provide for the preservation of the designated area in perpetuity and shall include such terms, conditions, and financial endowments for monitoring and management deemed necessary by the County to ensure the long term preservation of the oak woodland within the easement area. The Conservation Easement shall be in favor of the County or a County approved conservation organization.

8. Ministerial Projects on Existing Legal Lots for which Previous Approvals or Determinations of Developable Area have been made by County Decision-Makers: Previously approved discretionary projects that have conditions of approval and/or mitigation measures specifying detailed oak tree protection and mitigation plans shall not be required to demonstrate further consistency with Policy 7.4.4.4. However, canopy that was required to be retained in prior approvals must continue to be retained, unless modified by the decision-making authority for the original protection plan. This provision does not apply to any development project whose approval has expired and a time extension is applied for.

Reasonable Use Provisions for Development on Existing Legal Lots

- A. Reasonable Use Related to Oak Canopy Cover Retention:

For existing legal lots, where strict compliance with the oak canopy cover retention requirements of Policy 7.4.4.4 could preclude reasonable use of the property or cause substantial inconsistencies with other General Plan policies protective of the environment, due to factors which are unique to the proposed property, such as topographic constraints, configuration of the remaining area useable for development, access requirements, lot size, and/or other physical or environmental limitations, or conflict with the requirements of an approved Fire Safe Plan, the Development Services Director may grant relief as described below, or the Planning Commission may grant relief to the retention requirements of Policy 7.4.4.4 for the project if the following findings are made pursuant to a noticed public hearing:

Development Services Director Relief:

The Director may grant a reduction in the retention requirements by up to 50 percent of what is specified in the Option A Retention Table after meeting all the required findings herein (subsection i. through iv.) and meeting one of the following conditions.

- For existing legal lots ½ acre in size or less with up to 100 percent disturbed area proposed; or
- For existing legal lots greater than ½ acre up to one acre in size with not more than 20,000 square feet of development/disturbed area proposed; or
- For existing legal lots greater than one acre in size but not greater than five acres in size with not more than 25,000 square feet of development/disturbed area proposed, excluding driveway access

removing oak canopy (intrusion of up to 25 percent of the dripline permitted).

- For existing legal lots greater than five acres with not more than 30,000 square feet of development/disturbed area proposed excluding driveway access removing oak canopy (intrusion of up to 25 percent of the dripline permitted).

If the lot is within an Important Biological Corridor or Ecological Preserve, relief may only be granted by the Planning Commission.

Planning Commission Relief:

Where the Director cannot grant relief, the Commission may grant relief when the following findings can be made.

- i. The applicant demonstrates that the project is designed to maximize use of parcel area unconstrained by oak trees, unless precluded by other significant constraints such as steep slopes, streams, creeks, wetlands, or other sensitive environmental resources.
- ii. The proposed project is limited to development and site disturbance that is typical and prevalent for the general area surrounding the project site.
- iii. Soil disturbance and tree removal is minimized through the incorporation of some or all of the following measures into the project design:
 - a. Stepped foundations are used on sloping areas rather than graded pads;
 - b. Depth of excavation and/or fill outside of the building footprint is limited to no more than five feet measured vertically from the natural ground surface, except for grading necessary to install retaining walls designed to reduce the total area of tree canopy that will be removed and/or damaged;
 - c. Structures and the configuration of the area of disturbance are designed to parallel the natural topographic contours to the greatest extent feasible;
 - d. Patio decks are included in the design of dwellings to minimize the need for graded yard areas;

- e. Design techniques such as clustering of buildings are proposed to take advantage of the portions of the property which are least constrained by oaks;
 - f. The project is designed to maximize consistency with all applicable policies of the El Dorado County General Plan. *It is recognized that more than one policy may have to be considered in the determination of reasonable use of a particular parcel.*
- iv. If the project site is within ~~or directly adjacent to~~ an Important Biological Corridor Overlay or Ecological Preserve a Biological Resources Study and Important Habitat Mitigation Program have been prepared by a qualified professional and approved by the County and will be fully implemented by the applicant. The Study shall be prepared in accordance with the *Biological Resources Study and Important Habitat Mitigation Program Interim Guidelines*, adopted November 9, 2006.

Replacement of any oak tree canopy area allowed to be removed by the Planning Commission in excess of the retention standards in the General Plan shall be required. At a minimum, the replacement shall be completed in accordance with the tree replacement formula. Refer to the 1:1 Woodland Replacement definition. A 2:1 ratio or as otherwise specified by a qualified professional approved by the County, pursuant to the options and methods specified in these Guidelines, may be applied at the discretion of the Planning Commission. Further, for discretionary projects, any effects on biological resources will be analyzed in the environmental document and appropriate additional mitigation proposed as required by the California Environmental Quality Act, California Oak Woodlands Conservation Law and other applicable statutes.

B. Reasonable Use Related to Oak Corridor Retention:

In order to ensure that reasonable use of the property is provided, an applicant may request the Planning Commission to provide relief from the strict application of this corridor retention requirement (Policy 7.4.4.5) in the same manner as described above. In addition, for discretionary projects, any effects on biological resources will be analyzed in the environmental document and appropriate mitigation proposed as required by the California Environmental Quality Act, California Oak Woodlands Conservation Law and other applicable statutes.

GENERAL REQUIREMENTS APPLICABLE TO ALL PROJECTS

Compliance with the General Plan:

In addition to compliance with these guidelines for these Policies, the proposed development shall be in conformance with all other applicable policies of the County General Plan and any applicable Specific Plans and/or Development Agreements.

Compliance with the Zoning Ordinance and Grading Ordinance and Building Codes:

The proposed development shall be in compliance with all applicable requirements of the County Zoning Ordinance, Grading Ordinance, and Building Codes.

County, State, or Federal Agency Requirements:

County, State and Federal agencies have different jurisdictional authority which may result in different conditions for approval. In the event of multiple agency permit approval, the most restrictive set of conditions shall apply.

Important Biological Corridor Overlay Designation and Ecological Preserve Overlay Designation:

Proposals for removal of any oak canopy cover on property within or directly adjacent to an Important Biological Corridor Overlay (IBC) designation or Ecological Preserve Overlay (EP) designation pursuant to the General Plan shall require review by the Planning Commission to ensure consistency with the requirements of Policies 7.4.2.9 and 7.4.1.4. A Biological Resource Study and Important Habitat Mitigation Program shall be required.

SITE ASSESSMENT FORM REQUIREMENTS AND THE TREE SURVEY, PRESERVATION, AND REPLACEMENT PLAN REQUIREMENTS

The Site Assessment Form requirements are detailed in Attachment 1.

BIOLOGICAL RESOURCE STUDY AND IMPORTANT HABITAT MITIGATION PROGRAM REQUIREMENTS

Biological Resource Study and Important Habitat Mitigation Program requirements are detailed in Attachment 2.

ADMINISTRATION

The above guidelines are interim standards utilized by the Development Services Department of El Dorado County to provide for consistent review of projects for conformance with Policy 7.4.4.4 pending adoption of permanent regulations.

~~Penalties for Violation – Pursuant to Policy 7.4.5.2 D, If oak trees are removed prior to review by the County and without appropriate retention and replacement provisions implemented in anticipation of development of a site, the County may withhold and defer approval of any application for development of that property for a period of up to five years. Additionally, fines may be applied as high as three times the current market value of replacement trees plus the cost of replacement, and/or replacement tree(s) may be required at a 3:1 ratio at sites approved by the County. The cost of maintenance, monitoring, and reporting of any replacement trees shall be paid for by the applicant. until such time as the amount of oak tree canopy removed is determined and appropriate replacement and mitigation provisions are met in conformance with Policy 7.4.4.4 to the satisfaction of the Director.~~

Natural Resources Conservation Service Descriptions for Soils Observed During Field
Surveys

Natural Resources Conservation Service Descriptions for Soils Observed During Field Surveys

SOBRANTE SERIES

The Sobrante series consists of moderately deep, well drained soils that formed in material weathered from basic igneous and metamorphic rocks. These soils are on foothills and have slopes of 2 to 75 percent. The mean annual precipitation is about 32 inches and the mean annual temperature is about 60 degrees F.

TAXONOMIC CLASS: Fine-loamy, mixed, active, thermic Mollic Haploxeralfs

TYPICAL PEDON: Sobrante silt loam, rangeland. (Colors are for dry soil unless otherwise noted.)

A--0 to 5 inches; reddish brown (5YR 5/4) silt loam, dark reddish brown (5YR 3/4) moist; massive; slightly hard and hard, friable, slightly sticky and slightly plastic; many very fine roots; common very fine and medium tubular and interstitial pores; moderately acid (pH 6.0); clear smooth boundary. (4 to 9 inches thick)

Bt1--5 to 11 inches; yellowish red (5YR 4/6) silt loam, yellowish red (5YR 3/6) moist; weak medium subangular blocky structure; hard, friable, sticky and slightly plastic; common very fine roots; many very fine and fine tubular pores; few thin clay films in pores; slightly acid (pH 6.3); clear smooth boundary. (5 to 10 inches thick)

Bt2--11 to 24 inches; yellowish red (5YR 5/6) light clay loam, dark red (2.5YR 3/6) moist; moderate medium subangular blocky structure; hard, friable, sticky and slightly plastic; common very fine roots; common very fine, many fine and medium tubular pores; many thin clay films in pores and on peds; slightly acid (pH 6.3); clear wavy boundary. (11 to 18 inches thick)

Cr--24 to 30 inches; soft well-weathered basic schist, slightly acid (pH 6.5). (0 to 6 inches thick)

R--30 to 34 inches; hard basic schist with pockets of slightly weathered schist.

TYPE LOCATION: El Dorado County, California; 2.5 miles south of Shingle Springs, 200 feet west of French Creek Road, 200 feet south of the N 1/4 corner of sec. 19, T. 9 N., R. 10 E.

RANGE IN CHARACTERISTICS: Depth to a lithic contact ranges from 20 to 40 inches and is variable over short distances. The soils between depths of about 5 to 15 inches are usually moist but become dry in all parts in May or early June and remain dry until October to mid-November. Coarse fragments throughout the profile range from about 3 to 30 percent with the largest amount usually in the uppermost and lowermost horizons. The mean annual soil temperature is 59 degrees to 66 degrees F. The soil is slightly or moderately acid throughout. The A horizon has dry colors of 7.5YR 5/2, 5/4, 5/6, 5/8, 4/4; 5YR 5/3, 5/4 and moist colors of 7.5YR 2/4, 3/2, 3/4; 5YR 3/3 or 3/4. Moist colors of 2/4, 3/2, and 3/3 are usually to a depth of 5 inches or less. It is silt loam, loam or gravelly loam with 10 to 25 percent clay. Organic matter ranges from 3 to 7 percent in the upper few inches and from 1.5 to 3 percent at 5 inches. The Bt horizon has dry colors of 2.5YR 5/6, 5/8; 5YR 5/8, 5/6, 4/6, 4/4, 3/4, 3/6; or 7.5YR 5/6 and moist colors of 2.5YR 3/6, 4/6, 4/8; 5YR 3/4, 4/4, 3/6; or 7.5YR 3/4. It is loam, silt loam, clay loam, silty clay loam, gravelly loam or gravelly clay loam with 25 to 35 percent clay and with a 4 to 15 percent (absolute) increase over the A horizon. Base saturation ranges from 70 to 90 percent. Some pedons lack a Cr horizon above the lithic contact.

Natural Resources Conservation Service Descriptions for Soils Observed During Field Surveys

COMPETING SERIES: These are the Academy, Burchell, Cajalco, Coarsegold, Honn, Jacinto, Modesto, Olashes, Perkins, and Pleasanton, Rescue, Sobay, Trimmer and Whitney series. Academy, Burchell, Coarsegold, Honn, Jacinto, Modesto, Perkins, Pleasanton and Rescue and Sobay soils lack a lithic contact above depth of 40 inches. Cajalco, Trimmer and Whitney soils have a paralithic rather than a lithic contact.

GEOGRAPHIC SETTING: The Sobrante soils are on foothills and have slopes of 2 to 75 percent. Elevation ranges from 125 to 3,500 feet. They formed in material weathered from basic igneous and metamorphic rocks, mainly amphibolite schist, diabase, andesite, or basalt. Rock outcrops are common. The climate is moist subhumid with warm dry summers and cool moist winters. Mean annual precipitation is 15 to 50 inches. Mean annual temperature is about 56 to 60 degrees F; average January temperature about 45 degrees F; and average July temperature about 76 degrees F. Frost-free season is about 200 to 270 days, but may be as few as 140 in Lake Co.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the Argonaut, Auburn and Boomer soils and the competing Rescue soils. Argonaut soils have more than 35 percent clay in the argillic horizon. Auburn soils have a lithic contact within a depth of 20 inches in part of each pedon. Boomer soils are in cooler sites with a mean soil temperature of less than 59 degrees F.

DRAINAGE AND PERMEABILITY: Well drained; low to very high runoff; moderate permeability.

USE AND VEGETATION: Used mainly for range, some areas are used for irrigated hay and pasture and dry land crops. The native vegetation is oak-grass and forbs with some scattered perennial grasses.

DISTRIBUTION AND EXTENT: Coast Range mountains and foothills of the Sierra Nevada Range in California. The series is of moderate extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Davis, California

SERIES ESTABLISHED: Contra Costa County, California, 1935.

REMARKS: The activity class was added to the classification in January of 2003. Competing series were not checked at that time. - ET

National Cooperative Soil Survey
U.S.A.

AUBURN SERIES

The Auburn series consists of shallow to moderately deep, well drained soils formed in material weathered from amphibolite schist. Auburn soils are on foothills and have slopes of 2 to 75 percent. The mean annual precipitation is about 24 inches and the mean annual temperature is about 60 degrees F.

TAXONOMIC CLASS: Loamy, mixed, superactive, thermic Lithic Haploxerepts

Natural Resources Conservation Service Descriptions for Soils Observed During Field Surveys

TYPICAL PEDON: Auburn silt loam - on an east facing slope of 10 percent under annual grass, oak and digger pine at 620 feet elevation. (Colors are for dry soil unless otherwise stated. When described on March 27, 1959, the soil was dry throughout.)

A1--0 to 1.5 inches; strong brown (7.5YR 5/6) silt loam, reddish brown (5YR 4/4) moist; massive; slightly hard, friable, slightly sticky and nonplastic; many very fine roots; many very fine and fine tubular pores; slightly acid (pH 6.4); clear smooth boundary. (1 to 8 inches thick)
A2--1.5 to 9 inches; yellowish red (5YR 5/6) silt loam, reddish brown (5YR 4/4) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; many very fine and medium roots; many very fine and medium tubular pores; slightly acid (pH 6.4); gradual smooth boundary. (1 to 8 inches thick)

Bw--9 to 14 inches; yellowish red (5YR 5/8) silt loam, yellowish red (5YR 4/6) moist; massive; slightly hard, friable, slightly sticky and slightly plastic; many very fine roots; many very fine tubular pores; few thin clay films line pores; slightly acid (pH 6.5); abrupt wavy boundary. (5 to 12 inches thick)

R--14 to 24 inches; very pale brown (10YR 7/4) partly weathered amphibolite schist with reddish brown (2.5YR 4/4) colloidal stains in fracture planes; few roots in cracks; slightly acid (pH 6.5).

TYPE LOCATION: Amador County, California. About 3.5 miles northeast of Lone, 0.25 miles east and 100 feet north of the southeast corner of sec. 6 T. 6 N, R. 10 E. Irish Hill Quadrangle.

RANGE IN CHARACTERISTICS: The depth to bedrock ranges from 10 to 28 inches. These range from less than 20 inches to more than 20 inches within a linear distance of less than 140 inches. Dominantly the soils are 10 to 20 inches deep to rock over 50 to 90 percent of the area. The rest of the area, 10 to 50 percent, is 20 to 28 inches to rock. The contact with the bedrock is abrupt, although some slightly weathered fracture planes are present in some pedons. Rock fragments range from 0 to 25 percent and consist of pebbles, cobbles and stones. The soil between the depths of 8 and 20 inches or to a lithic contact is dry in all parts from June to mid-October and is moist in all parts from mid-November to May. The mean annual soil temperature is between 59 and 67 degrees F.

The A horizon is 7.5YR 4/4, 5/8, 5/6, 5/4, 6/6; 5YR 4/6, 5/4 or 5/6. Moist colors are 7.5YR 3/2, 3/3, 3/4, 4/4, 4/6, 5/4; 5YR 3/3, 3/4, 3/6 or 4/4. Mottles of lower chroma than the matrix may occur in the upper 2 or 3 inches. It is massive or has weak subangular blocky structure. It is loam, silt loam or clay loam or its gravelly, stony, or very stony equivalents. It is neutral to medium acid.

The Bw horizon is 7.5YR 4/4, 5/4, 5/6, 5/8, 6/6; 5YR 4/4, 4/6, 5/4, 5/6, 5/8, 6/6 or 6/8. Moist colors are 7.5YR 4/4, 4/6, 5/4, 5/6, 5/8, 6/6, 6/8; 5YR 3/4, 4/4, 4/6, 5/6, 5/8, 6/6 or 6/8. It is loam, silt loam, clay loam, or its' gravelly equivalent. It is slightly to strongly acid. It has hues that are one unit redder or chromas that are brighter or there is weak structure or there is a slight clay increase.

COMPETING SERIES: These are the Daulton, Escondido, Exchequer, Hornitos, Maymen, eMillsholm, Sobrante, Temescal, and Toomes soils in other families. All these soils except Escondido and Sobrante are less than 20 inches deep to a lithic contact in all parts. In addition,

Natural Resources Conservation Service Descriptions for Soils Observed During Field Surveys

Daulton, Millsholm, and Temescal soils lack reddish colors in hues of 7.5YR and 5YR. Exchequer soils are less than 10 inches deep. Hornitos and Maymen have a base saturation (ammonium acetate) of less than 60 percent throughout the 10 to 20 inch zone. Escondido and Sobrante soils are more than 20 inches deep to a lithic contact in all points. In addition, Sobrante soils have an argillic horizon.

GEOGRAPHIC SETTING: The Auburn soils are on undulating to very steep foothills with slopes of 2 to 75 percent. Rock outcrops are common. The soils formed in material weathered from metabasic or metasedimentary rock such as amphibolite schist, greenstone schist, or diabase. Elevations are 125 to 3,000 feet. The climate is subhumid with hot dry summers and cool moist winters. Mean annual precipitation is 20 to 40 inches. Mean January temperature is about 45 degrees F, and mean July temperature is 76 degrees F; mean annual temperature varies from 56 to 63 degrees F. Frost-free season is about 175 to 275 days.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the competing Exchequer and Sobrante soils and the eArgonaut and Whiterock soils. Argonaut soils have argillic horizons and Whiterock soils lack reddish colors in hues of 7.5YR and 5YR.

DRAINAGE AND PERMEABILITY: Well drained; low to very high runoff; moderate permeability.

USE AND VEGETATION: Used for annual rangeland with small areas used for irrigated pasture. The native vegetation is typically annual grasses and forbs such as soft chess, wild oats, ripgut brome, and filaree with stands of oak and scattered digger pine and brush.

DISTRIBUTION AND EXTENT: Lower foothills of the Sierra Nevada Mountains of California. The soil is extensive.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Davis, California
SERIES ESTABLISHED: Marysville and Sacramento Areas, 1913. The classification was updated in February 2001 using the Eighth Edition to Soil Taxonomy. This series was formerly classified as loamy, oxidic, thermic Ruptic-Lithic Xerochrepts. Competing series were not checked at that time.

REMARKS: Diagnostic horizons and features recognized in this pedon are:
Ochric epipedon - 0 to 9 inches (A1, A2)
Cambic horizon - 9 to 14 inches (Bw)
Lithic contact - depth to contact in 10 to 28 inches and is more than or less than 20 inches within short distances.
Last major revision by the state on 5/88.
Edit log: 10/2006 minor edits, changed terminology for runoff

ADDITIONAL DATA: Two pedons in Amador County: NSSL Pedon S59CA-005-007 (series type location) and S59CA-005-008. Based on lab data this soil should NOT be oxidic and is mixed.

National Cooperative Soil Survey
U.S.A.

Natural Resources Conservation Service Descriptions for Soils Observed During Field Surveys

ARGONAUT SERIES

The Argonaut series consists of moderately deep, well drained soils that formed in materials weathered from meta-andesite. Argonaut soils are on foothills with slopes of 2 to 30 percent. The mean annual precipitation is 27 inches and the mean annual temperature is about 60 degrees F.

TAXONOMIC CLASS: Fine, mixed, superactive, thermic Mollic Haploxeralfs

TYPICAL PEDON: Argonaut gravelly loam-on a southwest facing slope of 6 percent under annual grass - oak cover at 1,360 feet elevation. (Colors are for dry soil unless otherwise stated. When described on March 24, 1959, the soil was slightly moist throughout.)

A1--0 to 2 inches; brown (7.5YR 5/4) gravelly loam, dark reddish brown (5YR 3/4) moist; weak thin platy structure; hard, friable, nonsticky and nonplastic; many very fine, few fine and medium roots; many very fine pores; 21 percent pebbles; slightly acid (pH 6.1); abrupt smooth boundary. (2 to 3 inches thick)

A2--2 to 6 inches; yellowish red (5YR 5/6) gravelly loam, yellowish red (5YR 3/6) moist, massive; hard, friable, nonsticky and slightly plastic; common very fine, few fine and medium roots; common very fine and fine, few medium pores; few thin clay films line pores; 20 percent pebbles, cobbles and stones; slightly acid (pH 6.3); clear smooth boundary. (3 to 8 inches thick)

Bt1--6 to 10 inches; yellowish red (5YR 4/6) gravelly heavy loam, yellowish red (5YR 3/6) moist, massive; hard, friable, slightly sticky and plastic; common very fine, few fine and medium roots; common very fine and fine medium pores; common thin clay films line most pores; 15 percent pebbles, cobbles and stones; slightly acid (pH 6.2); clear smooth boundary. (3 to 6 inches thick)

Bt2--10 to 14 inches; yellowish red (5YR 5/6) clay loam, yellowish red (5YR 3/6) moist; massive; hard, firm, slightly sticky and plastic; few fine and medium roots; common very fine and fine, few medium pores; continuous thin clay films line pores; about 8 percent pebbles and cobbles; slightly acid (pH 6.1); abrupt boundary. (3 to 5 inches thick)

Bt3--14 to 21 inches; brown (10YR 5/3) gravelly clay, yellowish brown (10YR5/4) and brown (7.5YR 5/4) moist; brown (7.5YR 5/4) coatings; massive; very hard, firm, sticky and very plastic; few very fine and coarse roots; few very fine pores; continuous thick clay films line pores; few slickensides; about 22 percent pebbles, cobbles and stones; slightly acid (pH 6.1); abrupt wavy boundary. (4 to 17 inches)

Cr--21 to 27 inches; light reddish brown (2.5YR 6/4) deeply weathered meta-andesite, light olive brown moist, yellowish red (5YR 4/6) moderately thick, continuous clay films and black stains along a few fracture planes; the weathered rock crumbles when disturbed but is firmer with increasing depth; neutral (pH 7.1).

TYPE LOCATION: Amador County, California; about 0.5 miles west of Martell, 1,800 feet south and 1,500 feet east of the NE corner of sec 19, T. 6 N, R. 11 E. Jackson Quadrangle.

Natural Resources Conservation Service Descriptions for Soils Observed During Field Surveys

RANGE IN CHARACTERISTICS: Thickness of solum and depth to a paralithic contact is 20 to 40 inches. The mean annual soil temperature ranges from 59 to 67 degrees F. The soil between the depths of 8 and 24 inches or to a paralithic contact is dry in all parts from June 1 to October 15 (120 to 150 days) and is moist in all parts from November 15 to May 15 (165 to 195 days). Some rock fragments are present throughout the soil with about 2 to 25 percent in the lower Bt horizons and 5 to 35 percent in the A and upper Bt horizons. It has 2 to 6 percent organic matter in the upper 4 inches and more than 1 percent to a depth of 10 inches. The weighted average of the upper 20 inches of the Bt horizon is 35 to 50 percent.

The A horizon is 7.5YR 6/6, 5/6, 5/4, 4/6, 4/4; 5YR 5/3, 5/4, 5/6, 4/6, 4/4, or 4/6. Moist colors are 7.5YR 3/4, 4/4, 4/6; 5YR 3/4, 4/3, 4/4, or 4/6. The upper 4 inches have moist color values of 3. It is loam, silt loam or clay loam and may be gravelly or extremely stony. It is massive and hard or the upper few inches has weak platy, weak granular or weak subangular blocky structure. Reaction is moderately acid to neutral .

There is a transitional horizon between the A and B horizon or a gradual boundary occurs for the A horizon. The upper Bt horizon is 7.5YR 4/4, 4/6, 5/4, 5/6, 5/8; 5YR 5/3, 5/4, 5/6, 4/4, or 4/6. Moist colors are 7.5YR 4/4, 4/6; 5YR 4/4, 4/6, or 3/4. It is heavy loam, heavy silt loam, clay loam or its gravelly or cobbly equivalents. Reaction is moderately acid to neutral. An abrupt boundary is always present.

The lower Bt horizon is 10YR 5/3, 5/4, 5/6, 6/4; 7YR 5/4, 5/6, 4/6, 4/4; 5YR 4/6, 5/6, or 4/4. Moist colors are 10YR 5/3, 5/4, 5/6; 7.5YR 5/6, 5/4, 4/4, 4/6; 5YR 3/4, 4/4, 4/6, 4/8, or 5/6. It is heavy clay loam, gravelly clay or clay. Reaction is moderately acid to mildly alkaline. The clay increase between the upper Bt and lower Bt exceeds 15 percent. In some profiles a stone line separates these two horizons.

The Cr is 10YR 7/6, 2.5Y 7/4, or 6/4. Moist colors are 2.5Y 6/4 or 5/4.

COMPETING SERIES: These are the Conosta, Contra Costa, Francker, Kilaga, Phipps (T), and Trabuco. Conosta soils lack an argillic horizon with more than 15 percent clay increase within one inch. Contra Costa soils have a lithic contact between 20 and 40 inches. Francker soils have a CA/Mg ratio of less than 2:1. Kilaga and Phipps (T) soils are greater than 60 inches deep. Trabuco soils have a paralithic contact below 40 inches.

GEOGRAPHIC SETTING: The Argonaut soils are on undulating to hilly broad ridges and slightly concave slopes of 2 to 30 percent. The soils formed in material weathered from metamorphosed and intrusive basic rocks. Rock outcrops are common. Elevations are 200 to 2,500 feet. The climate is subhumid with hot dry summers and cool moist winters. Mean annual precipitation is 20 to 50 inches. Mean January temperature is about 44 degrees F.; mean July temperature is about 76 degrees F.; mean annual temperature is about 56 to 63 degrees F. Frost-free season ranges from 220 to 270 days.

GEOGRAPHICALLY ASSOCIATED SOILS: These are the Auburn, Rescue and Sobrante soils. Auburn soils lack argillic horizons. Rescue and Sobrante have less than 35 percent clay in all parts of the argillic horizon.

DRAINAGE AND PERMEABILITY: Well drained; slow to rapid runoff; very slow permeability.

Natural Resources Conservation Service Descriptions for Soils Observed During Field Surveys

USE AND VEGETATION: Mainly used for annual rangeland. Vegetation is soft chess, wild oats, ripgut brome, filaree with scattered foothill pine and scattered to dense thickets of blue oak, interior live oak and buckbrush.

DISTRIBUTION AND EXTENT: Foothills of the central Sierra Nevada in California. The series is of moderate extent.

MLRA SOIL SURVEY REGIONAL OFFICE (MO) RESPONSIBLE: Davis, California

SERIES ESTABLISHED: Amador County, California, Amador Area 1963.

REMARKS: Diagnostic horizons and features recognized in the pedon are:

Ochric epipedon - 0 to 6 inches (A1, A2)

Argillic horizon - 6 to 21 inches (Bt1, Bt2, Bt3)

Paralithic contact at 21 inches.

This pedon was sampled by NSSL at Riverside in 1959. Pedon number S59CA-3-6-(1-6)

OSED scanned by SSQA. Last revised by state on 8/85.

Edit log: 4/2003 Proposed edits for use in Butte County. Expand reaction A horizon: moderately acid to neutral. Expand reaction lower Bt horizon: from slightly acid to moderately acid. Add the following colors: A horizon-dry colors: 7.5YR 4/6 and 5YR 4/6. Upper Bt horizon-dry colors: 7.5YR 4/4, 4/6. Lower Bt horizon dry colors: 7.5YR 4/4, 4/6. Moist colors: 5YR 3/4. Cr horizon-dry: 10YR 7/6. Expand elevation from 300 to 200 feet. Expand MAT from 62 to 63 degrees F. Changed digger pine to foothill pine.

ATTACHMENT C

Proposed Guidelines for Acorn Collection, Storage and Planting

Guidelines for Acorn Collection, Storage, and Planting

Acorn Collection

- All acorns should be from a source local to the mitigation sites.
- Collect acorns over an interval of a few weeks from late summer to mid fall, when the acorns have ripened, but before they have all fallen from the trees. Acorns can be harvested when they can be easily dislodged from their caps by gentle twisting and when they start to drop from the trees.
- If feasible, collect acorns directly from trees, rather than the ground, since acorns that are on the ground readily lose their moisture and are subject to predation.
- Place acorns in loosely sealed plastic bags that allow some gas exchange. Discard obviously damaged or deformed acorns.
- Store acorns in refrigerator just above freezing (34 degrees to 38 degrees F) for no more than one to two months before planting.

Planting Site Preparation

- All planting should be done in late fall or early winter, as soon as the soil is moist down to a depth of four+ inches.
- Soak acorns from eight to 48 hours prior to planting. Discard all acorns that float. Keep acorns cool during transport. Soaked acorns not planted must be discarded.
- Each planting site should be cleared of most vegetation around a four foot diameter area. Clear down to stubble and rake clean.
- Clear the center 12 inches of the planting site down to soil, removing all vegetation.
- Dig or auger a 12 inches deep planting hole in this center area, removing all but very small rocks and debris. If shallow hardpan is found within the planting site, auger past the depth of the hardpan.
- Backfill with the loosened soil or, if necessary, sterile topsoil to fill the planting hole back up to original grade. Compact well using foot and hand tools. Do not compact by machine.

Planting

- Over the backfilled planting hole, place four evenly spaced acorns of the species specified on their sides and within a six inch diameter circle. The acorns should be spaced in an area smaller than the diameter of the specified tree shelter.
- Cover the acorns with one to two inches of the specified topsoil. Carefully but thoroughly compact backfill with hand or foot.
- Place the specified tree shelter over the covered acorns, inserting the bottom of the shelter four inches into the soil if vole predation is a consideration.
- Place shredded or chipped wood mulch four inches deep or sterile rice straw (compressed with foot) six inches deep outside of the shelter to cover the entire four foot diameter planting area.

Maintenance

- Maintain a four-foot wide weed-free area around each acorn planting site for a minimum of three years by mowing or weedeating in mid spring. Initiate weed control in spring before weed seeds ripen. Additional late-season mowing or weedeating may be necessary. The elimination of surrounding weeds is vital to maintaining soil moisture, eliminating competition for light and space, and discouraging herbivory.
- The need for mowing may be reduced by additional applications of mulch or straw or by the application of approved pre- or post-emergent herbicides.
- Check for predation around tree shelters. Adjust position of the shelters and methods of weed control, if necessary.

PLANTING OAK SEEDLING WITH SHELTER

ATTACHMENT F

Conceptual Irrigation Layout and Guidelines for Irrigating Oak Seedlings and Acorns

1. TO HELP ENSURE SUCCESS OF CANOPY COVER MITIGATION, PLANT OAK SEEDLINGS AT A DENSITY OF 400 TREES/ACRE.
2. SPACING SHALL BE EQUAL TO OR GREATER THAN 10' O.C.
3. PLANT IN UNDULATING (NOT STRAIGHT) ROWS TO MIMIC NATURAL PATTERN OF OAK WOODLAND.
4. TO ALLOW FOR ANNUAL MOWING, IRRIGATION MAINLINES & LATERAL LINES SHALL BE BURIED AND DISTRIBUTION LINES SHALL RUN IN ONE DIRECTION ONLY. SPACING BETWEEN DISTRIBUTION LINES SHALL EXCEED WIDTH OF MOWER.

4

CONCEPTUAL IRRIGATION LAYOUT FOR OAK SEEDLINGS & ACORNS

X:\2009-019-Gencomp\Landscapes\Oak seedling plant\Spacing.dwg - 4/7/2009 10:20:55 AM - Adobe PDF

1. AT THE BEGINNING OF THE DRY SEASON, WATER SEEDLINGS DEEPLY, MOISTENING THE SURROUNDING SOIL TO A DEPTH OF AT LEAST 2'.
2. WATER INFREQUENTLY AND DEEPLY DURING THE DRY SEASON. SEE BELOW FOR TYPICAL IRRIGATION SCHEDULE, WHICH IS MEANT AS A GUIDE TO DETERMINE IRRIGATION FREQUENCY. ACTUAL SCHEDULE WILL BE DEPENDENT ON SOIL TYPE, EXPOSURE, AND LOCALE OF PLANTINGS. FOR EACH SUBSEQUENT WATERING, MOISTEN SURROUNDING SOIL TO A DEPTH OF AT LEAST 1'. NEWLY PLANTD SEEDLINGS WILL REQUIRE MORE FREQUENT WATERINGS.
3. ON LARGE-TRACK PLANTINGS, USE SOIL MOISTURE SENSOR WITH REMOTE CONTROL READER TO GUAGE WHEN SOIL IS DRY AND PLANTINGS SHOULD BE WATERED.
4. WATER DELIVERY DURING EACH WATERING CYCLE MUST PROVIDE ENOUGH WATER TO MOISTEN SOIL WITHIN TREE SHELTER.

IRRIGATION SCHEDULE GUIDELINES FOR OAK SEEDLINGS & ACORNS

SEASON	GOAL	YEAR 1	YEAR 2	YEAR 3	YEAR 4
MID SPRING (TYPICALLY MID APRIL)	DEEP WATER, MOISTENING SOIL TO DEPTH OF 2'+.	ONCE	ONCE	ONCE	ONCE, IF NEEDED
EARLY SUMMER	DEEP WATER, MOISTENING SOIL TO DEPTH OF 1'+.	ONCE / 2 WEEKS	ONCE / 3 WEEKS	ONCE / 4 WEEKS	MONITOR ONLY
LATE SUMMER	DEEP WATER, MOISTENING SOIL TO DEPTH OF 1'+.	ONCE / 3 WEEKS	ONCE / 3-4 WEEKS	ONCE / 4 WEEKS IF NEEDED	MONITOR ONLY
FALL - MID SPRING	NO WATERING REQUIRED	NONE	NONE	NONE	SYSTEM DISCONNECTED

**Re: Sacred Lands Search and contacts for the Lime Rock Valley, Central El Dorado Hills, Village of Marble Valley Specific Plans
File Nos. SP12-0001, SP12-0002, and SP12-0003**

Dear Ms. Pilas-Treadway:

I am requesting a sacred lands search to identify the presence of any Native American cultural resources within the project area of each of the proposed specific plans in El Dorado County. I am also requesting a list of Native American contacts for the project area in order to request consultation in compliance with Senate Bill SB18. In the coming months, the County will be initiating the EIR process for these projects. For your reference and review, attached are each of specific plan area exhibits and maps depicting the quadrant identification and township and range (Exhibits A-D).

Your assistance and prompt feedback would be invaluable to this process. Should you have any questions, I can be reached directly at 530-621-5363 or via email at Rommel.Pabalinas@edcgov.us.

Cordially,

Mel Pabalinas, Senior Planner

Subject: Quadrant, Sections, Township for Specific Plans

Dear Ms. Fowler:

Thank you for contacting me. Per your request below are the quadrant, section, township information for the Central El Dorado Hills, Village of Marble Valley, and Lime Rock Valley Specific Plan. The information supplements the correspondence that I sent today and last week. Please let me know should you need any additional information.

Central El Dorado Hills Specific Plan

Quadrant: Clarksville
Sections: 1-3, 11, 34 and 35
Township: 10N 08E and 09N 08E

Village of Marble Valley Specific Plan

Quadrants: Clarksville, Folsom SE, Latrobe and Shingle Springs
Sections: 7-9, 16, 17, 20-22
Township: 09N 09E

Lime Rock Valley Specific Plan

Quadrant: Shingle Springs and Latrobe
Sections: 14-16, 22
Township: 09N 09E

RE: SB 18 Tribal Consultation and Sacred Lands File Check for the Lime Rock Valley, Central El Dorado Hills, Village of Marble Valley Specific Plans, File Nos. SP12-0001, SP12-0002, and SP12-0003; El Dorado County

Dear Mr. Pabalinas:

Government Code §65352.3 requires local governments to consult with California Native American tribes identified by the Native American Heritage Commission (NAHC) for the purpose of protecting, and/or mitigating impacts to cultural places. Attached is a consultation list of tribes with traditional lands or cultural places located within the boundaries of the above general plan amendment.

As a part of consultation, the NAHC recommends that local governments conduct record searches through the NAHC and California Historic Resources Information System (CHRIS) to determine if any cultural places are located within the area(s) affected by the proposed action. A record search of the Native American Heritage Commission *Sacred Lands File* indicates the potential of Native American cultural resources in the project vicinity that may be impacted. The site is on the *Shingle Springs* USGS quadrangle (Township 9 north, Range 9 east, section 9). The site is known as the *Boychuk Site*. It is also a recorded archaeological site, number CA-ELD-225. For specific information regarding this site, please contact the Singles Springs Rancheria. The tribe's telephone number is on the attached list. Local governments should also be aware that records maintained by the NAHC and CHRIS is not exhaustive. A tribe may be the only source of information regarding the existence of a cultural place.

If you receive notification of change of addresses and phone numbers from tribes, please notify me. With your assistance we are able to assure that our consultation list contains current information.

If you have any questions, please contact me at my email address: rw_nahc@pacbell.net.

Sincerely,

A handwritten signature in black ink, appearing to read "Rob Wood".

PLANNING DEPARTMENT

Dear Mel Pabalinas

The Most likely Descendant, Daniel Fonseca would like to initiate consultation process with El Dorado County, Development Services Department for the proposed Village of Marble Valley Specific Plan Project that is located in El Dorado County. Among other things, we would like this consultation to address the cultural and historic resource issues, pursuant to the regulations implementing Section 106 of the National Historic Preservation Act.

Prior to meeting we would like to request any and all completed record searches and or surveys that were done in or around the project area up to and including environmental, archaeological and cultural reports.

Please let this letter serve as a formal request for the Shingle Springs Band of Miwok Indians to be added as a consulting party in identifying any Traditional Cultural Properties (TCPs) that may exist within the project's Area of Potential Effects (APE).

Please contact Andrew Godsey, Assistant Cultural Resource Director, (530) 391-7091 agodsey@ssband.org or Angela Rivera, Administrative Assistant at (530) 698-1557 anrivera@ssband.org to schedule a consultation meeting pursuant to Section 106 of the NHPA.

Sincerely,

Daniel Fonseca
Cultural Resources Director
Tribal Historic Preservation Officer (THPO)
Most Likely Descendent (MLD)

RE: Cultural Resources Identification Effort at Marble Valley, El Dorado County, California, T9N, R9E, Section 8, 9, 16, 17, 20, and 21 (ECORP Project No. 2012-020).

Dear Ms. Pilas-Treadway:

ECORP Consulting, Inc. has been retained to assist in the planning of the development on the project indicated above. As part of the identification effort, we are seeking information from all parties that may have knowledge of or concerns with historic properties or cultural resources in the area of potential effect.

Included is a map showing the project area outlined. We would appreciate input on this undertaking from the Native American community with concerns about possible traditional cultural properties or potential impacts within or adjacent to the Area of Potential Effects. Please understand that this is not a request for location, data or any other information that may be deemed sensitive or confidential to individual Native Americans, Native American organizations, or Federally Recognized Tribes. Information on other parties that may have interests or concerns in the undertaking would be appreciated. Please fax your response to my attention at (916) 782-9134. If you have any questions, please contact me at (916) 782-9100.

Thank you in advance for your assistance.

Sincerely,

Lisa Westwood, RPA
Cultural Resource Manager

Re: Marble Valley, El Dorado County.

Dear Ms. Westwood:

A record search of the sacred land file has failed to indicate the presence of Native American cultural resources in the immediate project area. The absence of specific site information in the sacred lands file does not indicate the absence of cultural resources in any project area. Other sources of cultural resources should also be contacted for information regarding known and recorded sites.

Enclosed is a list of Native Americans individuals/organizations who may have knowledge of cultural resources in the project area. The Commission makes no recommendation or preference of a single individual, or group over another. This list should provide a starting place in locating areas of potential adverse impact within the proposed project area. I suggest you contact all of those indicated, if they cannot supply information, they might recommend others with specific knowledge. By contacting all those listed, your organization will be better able to respond to claims of failure to consult with the appropriate tribe or group. If a response has not been received within two weeks of notification, the Commission requests that you follow-up with a telephone call to ensure that the project information has been received.

If you receive notification of change of addresses and phone numbers from any of these individuals or groups, please notify me. With your assistance we are able to assure that our lists contain current information. If you have any questions or need additional information, please contact me at (916) 653-4038.

Sincerely,

Debbie Pilas-Treadway

RE: *Cultural Resources Identification Effort at Marble Valley, El Dorado County (ECORP Project No. 2012-020).*

Dear Mr. Daniels:

ECORP Consulting, Inc. is currently conducting a cultural resources inventory of a ~2,000-acre parcel located near El Dorado Hills in El Dorado County. The study is being conducted in advance of approval of the proposed Marble Valley project. The project area is situated in Section 8, 9, 16, 17, 20, and 21 of Township 9N, Range 9E, MDBM. For your reference, the boundaries of the project area are marked on the enclosed topographic quadrangle map.

The purpose of the study is to identify cultural resources that could be affected by the proposed project, as required by Section 106 of the National Historic Preservation Act (NHPA) and the California Environmental Quality Act (CEQA). The investigation included a records search conducted with the North Central Information Center at California State University-Sacramento and a search of the Native American Heritage Commission's Sacred Lands File. The search of the Sacred Lands file did not identify any known Native American cultural resources within the immediate project vicinity; however, the Commission provided us with your name and contact information.

As part of this study, ECORP would like to identify archaeological, historic resources, or locations that are of cultural importance to the local Native American community. We would appreciate any information you may have regarding Native American cultural resources located in or near the proposed project location that could be affected by the proposed development of the parcel. We invite you to offer comments on the project, and we will forward them to the Section 106 lead agency for consideration and appropriate action. The lead agency will respond to your comments as soon as the Section 106 process is initiated. At this time, however, cultural resources investigations are being conducted for project planning purposes only. ECORP is gathering information on potentially unrecorded cultural resources that might be affected by this project.

We encourage you to participate in this process, so that potential impacts to Native American resources can be proactively addressed and minimized to the greatest extent feasible. We would like to receive a response from you about this project within the next two weeks. If we have not heard from you within 30 days of the receipt of this letter, we will assume that you do not wish to comment on this project. If you have any questions, please feel free to call me at (916) 782-9100 or via email at lwestwood@ecorpc consulting.com. Thank you for your assistance and participation in this project.

Sincerely,

Lisa Westwood, RPA

RE: Cultural Resources Identification Effort at Marble Valley, El Dorado County (ECORP Project No. 2012-020).

Dear Lisa Westwood

The Most likely Descendant, Daniel Fonseca would like to initiate consultation process with ECORP Consulting, Inc. for the proposed Marble Valley Project located in El Dorado County. Among other things, we would like this consultation to address the cultural and historic resource issues, pursuant to the regulations implementing Section 106 of the National Historic Preservation Act.

Prior to meeting we would like to request any and all completed record searches and or surveys that were done in or around the project area up to and including environmental, archaeological and cultural reports.

Please let this letter serve as a formal request for the Shingle Springs Band of Miwok Indians to be added as a consulting party in identifying any Traditional Cultural Properties (TCPs) that may exist within the project's Area of Potential Effects (APE).

Please contact Crystal Dilworth, Cultural Resource Office Manager at 530-698-1471 to schedule a consultation meeting pursuant to Section 106 of the NHPA.

Subject: Marble Valley, No. 2012-020

Dear Ms. Westwood,

Thank you for requesting information regarding the above referenced project. The United Auburn Indian Community (UAIC) of the Auburn Rancheria is comprised of Miwok and Southern Maidu (Nisenan) people whose tribal lands are within Placer County and ancestral territory spans into El Dorado, Nevada, Sacramento, Sutter, and Yuba counties. The UAIC is concerned about development within its aboriginal territory that has potential to impact the lifeways, cultural sites, and landscapes that may be of sacred or ceremonial significance. We appreciate the opportunity to comment on this and other projects in your jurisdiction.

In order to ascertain whether or not the project could affect cultural resources that may be of importance to the UAIC, we would like to receive copies of any archaeological reports that have been, or will be, completed for the project. We also request copies of future environmental documents for the proposed project so that we have the opportunity to comment on potential impacts and proposed mitigation measures related to cultural resources. The UAIC would also like the opportunity to have our tribal monitors accompany you during the field survey. The information gathered will provide us with a better understanding of the project and cultural resources on site and is invaluable for consultation purposes.

The UAIC's preservation committee has identified cultural resources within your project area and in close proximity, and would like to request a site visit to confirm their locations and meet with you regarding this project. Thank you again for taking these matters into consideration, and for involving the UAIC early in the planning process. We look forward to reviewing the aforementioned documents as requested. Please contact Marcos Guerrero, Tribal Historic Preservation Officer, at (530) 883-2364 or email at mguerrero@auburnrancheria.com if you have any questions.

Sincerely,

David Keyser,
Chairman

SECTION 1 – PROJECT INTRODUCTION

1.1 INTRODUCTION

In December 2012, the El Dorado Irrigation District (EID) received a letter from the El Dorado County Planning Department (County) requesting the completion of a Water Supply Assessment (WSA) for the Village of Marble Valley Specific Plan (hereafter referred to as the “Proposed Project”). As the proposed water supply purveyor for the Proposed Project, EID has prepared this WSA to assess the availability and sufficiency of EID’s water supplies to meet the Proposed Project’s estimated water demands. This document provides the necessary information to comply with the assessment of sufficiency as required by statute.

Statutory Background

Enacted in 2001, Senate Bill 610 added section 21151.9 to the Public Resources Code requiring that any proposed “project,” as defined in section 10912 of the Water Code, comply with Water Code section 10910, et seq. Commonly referred to as a “SB 610 Water Supply Assessment,” Water Code section 10910 outlines the necessary information and analysis that must be included in an environmental analysis of the project (e.g. CEQA compliance) to ensure that proposed land developments have a sufficient water supply to meet existing and planned water demands over a 20-year projection.

Proposed “projects” requiring the preparation of a SB 610 water supply assessment include, among others, residential developments of more than 500 dwelling units, shopping centers or business establishments employing more than 1,000 persons or having more than 500,000 square feet of floor space, commercial office buildings employing more than 1,000 persons or having more than 250,000 square feet of floor space and projects that would demand an amount of water equivalent to, or greater than, the amount of water required by a 500 dwelling unit project.¹

The Proposed Project requires a WSA because it contemplates more than 500 new dwelling units as detailed in Section 1.2.

Document Organization

This WSA supports the Proposed Project’s environmental review process and analyzes the sufficiency of water supplies to meet projected water demands of the Proposed Project through the required planning horizon. The WSA is organized according to the following sections:

- ◆ **Section 1: Project Introduction.** This section provides an overview of WSA requirements, and a detailed description of the Proposed Project, especially the land-use elements that will require water service.

¹ Water Code § 10912, subdivision (a).

- ◆ **Section 2: Proposed Project Estimated Water Demands.** This section describes the methodology used to estimate water demands of the Proposed Project and details the estimated water demands at build-out of the Proposed Project.
- ◆ **Section 3: Other Estimated Water Demands.** This section details the other water demands currently served by EID and anticipated to be served based on information in the El Dorado County’s (County) General Plan as well as known and potential planned modifications since the County’s adoption of the General Plan.
- ◆ **Section 4: Water Supply Characterization.** This section characterizes the EID water supply portfolio that will serve the Proposed Project along with other current and future water demands. Water rights, along with water service contracts and agreements are characterized for normal, single dry, and multiple dry year conditions.
- ◆ **Section 5: Sufficiency Analysis.** This section assesses whether sufficient water will be available to meet the Proposed Project water demands, while recognizing existing and other potential planned water demands within the EID service area. To provide the necessary conclusions required by statute, the analysis integrates the demand detailed in Section 2 and Section 3 with the characterization of EID’s water supply portfolio detailed in Section 4.

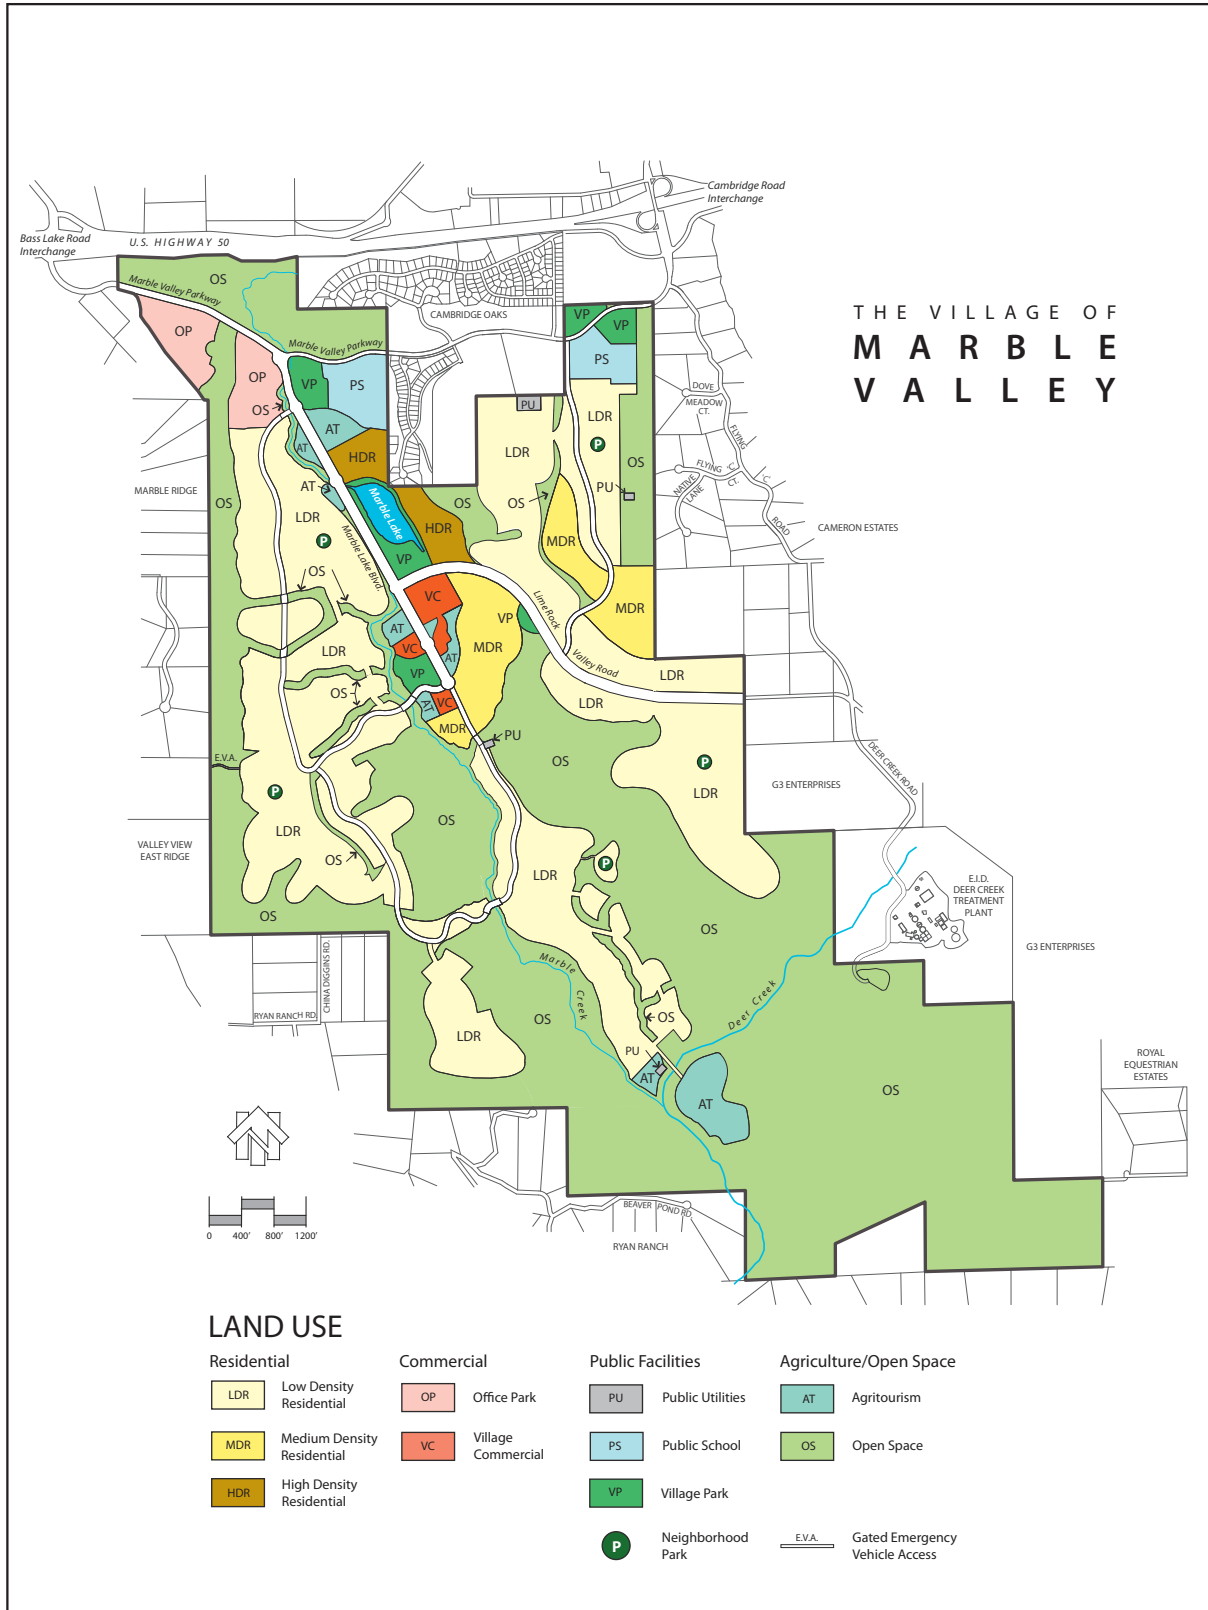

1.2 PROPOSED PROJECT DESCRIPTION

The Proposed Project is a planned development between Bass Lake and Cambridge Roads, south of Highway 50 encompassing approximately 2,340 acres in the unincorporated community of El Dorado Hills (see **Figure 1-1**).

The Proposed Project includes 3,236 residences, commercial space, village and neighborhood parks, agricultural uses, two schools, and open space. Proposed residential dwelling units include 193 custom lots on approximately 1 acre, 125 custom homes on approximately 1/2 acre-lots, 982 production lots with densities of 3 to 4 dwelling units per acre (designated “medium density-low”), 663 production lots with densities of 4 to 5 dwelling units per acre (designated “medium density-high”), 981 lots with densities of 7 to 12 dwelling units per acre (designated “Condo/Duplex”), and 292 high-density units (designated “multi-family”). Parks are spread throughout the project and include private parks in the gated areas, joint use parks along side the schools, village parks for non gated areas, a large park around the lake, and a historic park. The project includes about 475,000 square feet of commercial, retail, office, and other non-residential space residing on about 58 acres on the project site. Both a K5 and K8 school are planned for about 35 acres. About 55 acres of vineyards are to be planted on site both in designated lots and in some medians for aesthetics.

Table 1-1 summarizes the proposed land use acreages.

Figure 1-1 – Proposed Project Location and Land Uses

Torrence Planning

1.2.2 Projected Land Uses

Table 1-1 – Summary of Proposed Build-Out Land Uses and Acreages²

Land Use	Description	Acres	Units
1 Acre Custom Homes	1 DU/Ac	198	193
1/2 Acre Custom Homes	2 DU/Ac	62	125
3-4 per Acre Production Homes	3-4 DU/Ac	277	982
4-5 per Acre Production Homes	4-5 DU/Ac	148	663
Condominiums/Town Homes	5-12 DU/Ac	85	772
High Density Residential	12-24 DU/Ac	28	501
Office Park/Commercial	--	60	--
Schools	--	35	--
Parks	--	47	--
Open Space	--	1,282	--
ROW and Landscaping	--	73	--
Vineyards	--	55	--
	Total	2,350	3,236

1.3 PROPOSED PROJECT PHASING

Table 1-2 describes the Proposed Project’s four construction phases. Each phase represents a portion of the development, focusing on particular land-use classifications. Before constructing homes, commercial space, or other parts of the development, the proponents will begin site grading and project-wide infrastructure development. Some infrastructure and site grading will continue throughout all phases of the Proposed Project, as necessary. These activities include installing facilities for potable water, recycled water (as appropriate for the Proposed Project), sewer, electric, telecommunications, gas, stormwater, and roads. During these activities, a small water demand will exist – referred to in this WSA as “construction water.” This demand is included in the yearly water demands presented in Section 2.

The initial phase will result in approximately one quarter of the Proposed Project demanding water service by 2020, with the three subsequent phases each adding an additional quarter as they are completed. All construction is planned to be completed by 2035, within the 20-year planning horizon of this WSA.

² Specific Plan Land Use Summary was provided by El Dorado County of Development Services Department.

Table 1-2 – Proposed Project Schedule

Land Use	Phase 1 By 2020	Phase 2 2021-2025	Phase 3 2026-2030	Phase 4 2031-2035	Total
1 Acre Custom Homes	25	20	100	48	193
1/2 Acre Custom Homes	25	25	--	75	125
3-4 per Acre Production Homes	215	378	--	389	982
4-5 per Acre Production Homes	--	--	663	--	663
Condominiums/Town Homes	75	522	175	--	772
High Density Residential	209	50	228	14	501
Total	549	995	1,166	526	3,236

SECTION 2 – PROPOSED PROJECT ESTIMATED WATER DEMANDS

2.1 INTRODUCTION

This section describes the methodology, provides the supporting evidence, and presents the estimated water demands for the Proposed Project. For the purpose of estimating water demand, the Proposed Project is planned to develop according to the phasing in **Table 1-2**.

2.2 DETERMINING UNIT WATER DEMAND FACTORS

As detailed in Section 1, the Proposed Project has specific residential and non-residential land-uses with defined residential lot-sizes, types of commercial uses and other characteristics. As these attributes vary among the types of proposed land-uses, so too will the water needs. To understand the water needs of the entire Proposed Project, unique demand factors that correspond with each unique land use are necessary. This subsection presents the methodology for determining the baseline unit water use demand factors that become the basis of the Proposed Project water demand estimates. Two distinct groups of demand factors are presented: (1) residential, and (2) non-residential.

2.3 PRIMARY SOURCE OF BASELINE WATER USE DATA

Because the Proposed Project is very similar in nature to particular elements built as part of the Serrano and El Dorado Hills developments over the past few decades, recent water use data for comparable products in these neighborhoods provides a reliable foundation for EID to establish new project-specific water demands. Through comparison of Proposed Project land-use elements to existing land uses, EID determined appropriate existing, established neighborhoods and commercial facilities that best aligned with each unique residential and non-residential project element. For each comparable neighborhood, EID gathered and assessed total annual water use for the years 2008 through 2012. This selected period of water use best represents 1) the highest build-out percentage within each selected area (including established back-yard landscapes), and 2) varied water use over a range of climatic conditions reflecting various rainfall amounts and timing. Average annual uses were derived from the data and are discussed under the respective land-use categories.

2.4 BASELINE RESIDENTIAL WATER USE DEMAND FACTORS

The Proposed Project anticipates specific residential products that fall within general lot-size designations. The size of the lot will have the largest impact on the annual per-lot demand for water. Indoor demands remain relatively consistent regardless of lot size, with the exception of apartments, which tend to have fewer people living in each unit and thus a slightly lower indoor use.

For purposes of this WSA, the per-lot demand for residential lots will be described as “the acre-feet of water use annually per dwelling unit” – or simply put, acre-feet/dwelling unit (af/du). This value will reflect indoor and outdoor uses expected for a typical dwelling unit for each of the following classifications:³

- ◆ 1-acre custom lots
- ◆ ½-acre custom lots
- ◆ 8,000 to 10,000 square-foot production lots
- ◆ 5,000 to 7,000 square-foot production lots
- ◆ Condominiums/townhouses
- ◆ Multi-family housing with community facilities including pool and/or clubhouse

The method and basis for determining the baseline unit water demand factor for each of these classifications is detailed in the following subsections.

1-Acre Custom Home Lots

Water demand factors for the proposed large lots are based on recent water use data records for residential lots in the Serrano development – specifically existing residential lots located on Greenview Drive, Errante Drive, and others. The proposed lots in this category average at about 1 acre. However, not all land on these lots will be landscaped. For instance, a lot may include hillside and/or areas of oak woodland that must be protected, resulting in a diminished area for the home’s footprint, outdoor hardscapes and landscaping. Generally, the house itself is large, with extensive outdoor features including pools, hardscapes, water features, and significant landscaping with well-maintained turf areas.

Based on available historic meter data for similar developments served by EID, the baseline unit water demand factor for this land-use category is approximately 1.16 af/du.

½-Acre Custom Home Lots

Water demand factors for the proposed large lots are based on recent water use data records for residential lots in the Serrano development – specifically existing residential lots located on Renaissance Way and Renaissance Place. The proposed lots in this category average at about 1/2-acre though have a project minimum of 15,000 square feet. Landscaping on the lot may be based on a predetermined landscaping package for a production home. Generally, the house itself is large, with extensive outdoor features including pools, hardscapes, water features, and significant landscaping with well-maintained turf areas.

Based on available historic meter data for similar developments served by EID, the baseline unit water demand factor for this land-use category is approximately 0.87 af/du.

³ These classifications reflect EID’s defined water demand factor categories as EID believes they best relate to the Proposed Project’s land-use classifications as shown in the Table 1-1.

8,000 to 10,000 Square-foot Production Lots

The proposed project will include a large number of lots reserved for production homes on lots typically described as “large” for a residential community. For these lots, ranging up to ¼-acre or more, water demands will be based on recent water use data records for similar lots in the Serrano development – specifically Village D2 and portions of Village E, which includes numerous similar-sized lots. In contrast to the smaller lot production homes described in the next classification, these lots will retain adequate area on the lot for well-maintained turf and other landscaping. As much as one-half, but not less than about one-quarter, of the lot may still remain for landscaping, after accounting for the home’s footprint and hardscape areas – equating to a few thousand to several thousand square-feet. Though less landscaped area than the custom home lots, the landscaped area will drive water use on these lots.

Based on the available historic meter data for similar developments served by EID, the baseline unit water demand factor for this land-use category is 0.55 af/du.

5,000 to 7,000 Square-foot Production Lots

The Proposed Project includes numerous proposed lots with average of 4 to 5 dwelling units per acre. As a result of the limited outdoor area, many of these lots are limited to front-yard landscaping with well-maintained turf, and back yards often only including hardscapes, pools or other amenities, and lower water using landscapes. Unit water demands are based on recent water use data records for similar lots in the Serrano development – specifically Village D1A, portions of Village E and Euer Ranch, which include numerous similar-sized lots.

Based on the available historic meter data for similar developments served by EID, the baseline unit water demand factor for this land-use category is 0.50 af/du.

Condominiums/Townhouses

The Proposed Project includes numerous proposed lots characterized as being condominiums or townhomes (7 to 12 units per acre). These proposed lots are anticipated to be similar to projects in the El Dorado Hills area, most notable the Regalo Project in Serrano. The Proposed Project includes large attached housing units, with large individual landscape yards and common areas.

Based on the available historic meter data for similar developments served by EID, the baseline unit water demand factor for this land-use category is 0.40 af/du.

Multi-Family Housing

The Proposed Project includes numerous multi-family housing elements characterized as multi-family housing. These lots will include community landscaping, multi-story housing structures, community pools and other amenities. These projects are anticipated to be similar to the existing indoor and outdoor demands of the Sterling Apartment and Vineyard Apartment properties currently served by EID. Although both of these properties differ in their layouts and landscape

types and coverage, both use approximately the same quantity of water on a per-dwelling unit basis.

Based on the available historic meter data for similar developments served by EID, the baseline unit water demand factor for this land-use category is 0.16 af/du – inclusive of both indoor and outdoor demands.

Residential Indoor Water Use

Based on EID meter data for the past several years, indoor water use for typical single-family homes averages about 0.18 af/du.⁴ The value drops for apartments as a result of less people on average living in each apartment unit.⁵ This value can be used to derive separation of residential demands that could be served with non-potable supplies, such as recycled water from the Deer Creek and/or El Dorado Hills wastewater treatment facilities (see Section 2.7.2).

2.5 MODIFYING BASELINE VALUES

All of the above-developed water demand factors for the residential classifications are based on similar existing developments in the El Dorado Hills area. However, since construction of the existing houses, a few changes have occurred that will reduce the Proposed Project's water demands from the baseline unit water demands derived from existing meter data. These include:

- ◆ CAL Green Code
- ◆ California Model Water Efficient Landscape Ordinance

CAL Green Code

In January 2010, the California Building Standards Commission adopted the statewide mandatory Green Building Standards Code (CAL Green Code) that requires the installation of water-efficient indoor infrastructure for all new projects beginning January 1, 2011. CAL Green Code was incorporated as Part 11 into Title 24 of the California Code of Regulations.⁶ The CAL Green Code applies to the planning, design, operation, construction, use and occupancy of every newly constructed building or structure. All proposed land uses must satisfy the indoor water use infrastructure standards necessary to meet the CAL Green Code. The CAL Green Code requires residential and nonresidential water efficiency and conservation measures for new buildings and structures that will reduce the overall potable water use inside the building by 20 percent. The 20 percent water savings can be achieved in one of the following ways: (1) installation of plumbing fixtures and fittings that meet the 20 percent reduced flow rate specified in the CAL Green Code, or (2) by demonstrating a 20 percent reduction in water use from the building

⁴ This value is a subset of the total usage estimated for a dwelling unit under each land-use category. Data from 2012 Water Resources and Service Reliability Report, EID, August 13, 2012, Appendix Table A, p.42

⁵ El Dorado County indicates the average household size is 2.63 persons per occupied unit. (El Dorado County General Plan, 2008 Housing Element, August 2008 (Amended April 2009), p. 4-7).

⁶ The CAL Green Code is Part 11 in Title 24.

“water use baseline.”⁷ The Proposed Project will satisfy one of these two requirements through the use of appliances and fixtures such as high-efficiency toilets, faucet aerators, on-demand water heaters, as well as Energy Star and California Energy Commission-approved appliances.

California Model Water Efficient Landscape Ordinance

In 2006, the Water Conservation in Landscaping Act was enacted, which required the Department of Water Resources to update the Model Water Efficient Landscape Ordinance (MWELo).⁸ In fall of 2009, the Office of Administrative Law (OAL) approved the updated MWELo, which required that a retail water supplier adopt the provisions of the MWELo by January 1, 2010 or enact its own provisions equal to or more restrictive than the MWELo provisions.

The provisions of the MWELo are applicable to new construction with a landscape area greater than 2,500 square feet.⁹ The MWELo provides a methodology to calculate total water use based upon a given plant factor and irrigation efficiency. Finally, MWELo requires the landscape design plan to delineate hydrozones (based upon plant factors) and then assign a unique valve for each hydrozone (low, medium, high water use).¹⁰ The design of landscape irrigation systems is anticipated to better match the needs of grouped plant-types and thus result in more efficient outdoor irrigation.

Applying Conservation to Baseline Demand Factors

Collectively, these and other factors will put downward pressure on the baseline residential unit water demand factors – potentially dropping each unit demand by up to 10 percent for the larger lots. **Table 2-1** provides a summary of the baseline demand factor for each residential land-use category, the anticipated savings from the conservation mandates, and the resulting unit demand factor used to estimate the Proposed Project’s water use.

⁷ See CAL Green Code.

⁸ Gov. Code §§ 65591-65599

⁹ CCR Tit. 23, Div. 2, Ch. 27, Sec. 490.1.

¹⁰ CCR Tit. 23, Div. 2, Ch. 27, Secs. 492.3(a)(2)(A) and 492.7(a)(2).

Table 2-1 – Summary of Residential Baseline and Proposed Project Demand Factors

EID Water Demand Category (Relates to Table 1-1 Land Use)	Density Range	Current Factor (af/du)	Conservation Applied	Factor Used (af/du)
1 Acre Custom Homes	1 DU/Ac	1.16	10%	1.04
1/2 Acre Custom Homes	2 DU/Ac	0.87	8%	0.80
8,000-10,000 sf Lots	3 - 4 DU/Ac	0.55	5%	0.52
5,000-7,000 sf Lots	4 - 5 DU/Ac	0.50	5%	0.48
Condominiums/Town Homes	7 - 12 DU/Ac	0.40	4%	0.38
Multi-Family Housing ¹	15 - 24 DU/Ac	0.16	2%	0.16

1. The Multi-family Housing values remain constant due to rounding. The "current factor" was determined to be 0.165 af/du.

2.6 BASELINE NON-RESIDENTIAL WATER USE DEMAND FACTORS

Similar to the residential water demand factors, non-residential factors are based upon recent water use trends for similar types of land classifications.

For purposes of this WSA, the per-lot demand for non-residential lots is described as “the acre-feet of water use annually per acre of land” – or simply put, acre-feet/acre (af/ac). This value reflects indoor and outdoor water needs expected for a typical non-residential use for each of the following classifications:

- ◆ Office Park/Village Commercial
- ◆ Public and Neighborhood Parks
- ◆ Schools
- ◆ Other miscellaneous uses, including street medians, recreational lake, vineyards, and environmental mitigation

The method and basis for determining the baseline unit water demand factor for each of these classifications is detailed in the following subsections.

Office Park/Village Commercial

The proposed office park/village commercial facilities are anticipated to be “office space” as well as “retail and entertainment” in nature. Analysis of recent meter data for both the La Borgata retail facility on El Dorado Hills Boulevard and the Village Green office/public facility at the corner of Silva Valley and Serrano Parkways indicates that water use on a per-acre basis is nearly consistent, with the retail space using about 2.15 af/ac and the office facility using 1.95 af/ac. Although the Village Green indoor facilities have lower use, the area has more turf landscaped area (not including Village Green park), which matches, on a gross acre-by-acre comparison with the higher indoor retail demands and limited landscaping of the restaurants at La Borgata.

Based on the available historic meter data for similar facilities served by EID, the unit water demand factor is 2.0 af/ac.

Public and Neighborhood Parks

The Proposed Project includes five neighborhood parks, two village joint-use parks, and two special use parks. Neighborhood parks will include expansive turf areas, playfields, and other park amenities. Village joint-use parks will be adjacent to the school facilities and consist of similar features as the neighborhood parks. The special use parks, that surround the lake and historical site, differ from the other parks and are analyzed on a net landscaped acreage to match the water use estimates. Based upon recent water meter data for similar park facilities in the El Dorado Hills area – namely Bella Terra Park, Allan Lindsey Park, and the Village A, C, L3, and L4 parks – a representative water demand factor was identified. A “smart meter” controls the irrigation system at each existing park. These devices adjust water use to actual climate data, including precipitation events. Thus, the recent meter data is very indicative of expected demands for the new parks, which will also be outfitted with similar technology.

Based on the available historic meter data for similar facilities served by EID, the unit water demand factor is 2.77 af/ac.

Schools

The Proposed Project includes two schools: a Kindergarten through 5th grade, and a Kindergarten through 8th grade. The schools will use adjacent village parks for school-related recreational activities, and will include turf playfields. As an example, the water use at Oak Meadows Elementary on Silva Valley Parkway provides a useful representation of the expectations for the two proposed school facilities. Oak Meadows, operational by 2004, has an average water use of 1.70 af/ac – representing a use of about 0.019 af/student. For comparison, other schools in the area were analyzed and had very comparable per-student water use rates for similar facilities. But, the range in school use varied from as much as 2.5 af/ac to 0.8 af/ac – depending on factors like total school footprint, number of students and amenities. The average among seven schools analyzed was 1.43 af/ac. For purposes of this WSA, the average value would be an appropriate estimation for the future school sites.

Based on the available historic meter data for similar facilities served by EID, the unit water demand factor will use a baseline value of approximately 1.43 af/ac.

Other Miscellaneous Uses

The Proposed Project has additional miscellaneous uses including landscaped street medians, environmental mitigation requirements, a recreational lake, vineyards, gate houses at entrances to private streets, sewer lift stations, and construction water. These uses have minimal impacts to the overall per-project total water use due to their limited size and water needs, and some are temporary in nature.

Landscape Street Medians and Community Entrances

The Proposed Project includes proposed landscaping along street corridors and at entrances to particular residential areas, as is common in El Dorado Hills. Since comparable data is not available due to the variety of landscapes used in existing street medians around El Dorado Hills, unit water demands for this category is derived from the MWELo (see prior discussion under “residential land-uses”). To provide flexibility to the Proposed Project to landscape as needed, the entire width of the landscaped area was assumed to demand the maximum use allowed by MWELo.¹¹ This maximum is determined as 70 percent of the reference evapotranspiration for the area. Using available maps from the California Department of Water Resources, the reference evapotranspiration for the Proposed Project area is approximately 57 inches per year.¹² The resulting demand factor is 3.3 af/ac.

Oak Woodlands Management

As of the preparation of this WSA, the mitigation requirements for impacts to oak woodlands resulting from the Proposed Project are as detailed in the County’s Policy 7.4.4.4.¹³ For purposes of estimating the water demands of this Proposed Project element, the WSA assumes mitigation will include establishing new trees, likely with associated irrigation water to assure seedlings are established. As defined in the County’s Oak Woodland Management Plan Monitoring Program:

"Replacement of removed tree canopy . . . is subject to intensive to moderate management and 10 to 15 years of monitoring, respectively. The survival rate shall be 90 percent as specified in the approved monitoring plan for the project, prepared by a qualified professional. Acorns may be used instead of saplings or one gallon trees."

"Management intensity assumes that 10 years after planting 1 year old saplings that trees that have been nurtured with high management intensity will be on average 2 inches DBH with 90 percent survival; moderate management intensity will result in trees that are on average 1.5 inches DBH with 85 percent survival."

More precisely, an intensive management program is required to obtain 90 percent survival. The management includes 10 years of monitoring for one-gallon/one year old saplings and 15 years of

¹¹ Although this may be higher than seen by EID for current street medians and community entrances, this conservative assumption allows the Proposed Project with flexibility to landscape these areas up to the full demands of MWELo.

¹² Reference Evapotranspiration is obtained from the map available at <http://www.cimis.water.ca.gov/cimis/cimiSatEtoZones.jsp>

¹³ The County Board of Supervisors has an Oak Woodland Management Plan (OWMP) codified as Chapter 17.73 of the County Code (Ord. 4771. May 6, 2008.). The primary purpose of this plan is to implement the Option B provisions of Policy 7.4.4.4. On September 24, 2012, the Board of Supervisors directed the Development Services Department to prepare a General Plan amendment to amend Policies 7.4.2.8, 7.4.2.9, 7.4.4.4, 7.4.4.5, 7.4.5.1, and 7.4.5.2 and their related implementation measures to clarify and refine the County's policies regarding oak tree protection and habitat preservation. (This excerpt was copied from the following El Dorado County web site: http://www.edcgov.us/Government/Planning/General_Plan_Oak_Woodlands.aspx on May 4, 2013.)

monitoring if acorns are planted. Any trees/acorns that do not survive within the monitoring periods are to be replaced within that time, so that 90 percent survival is achieved at the end of the monitoring period.

Because establishment of new trees is highly dependent on site conditions (soil depth and composition, depth to water table, slope, aspect, existing vegetation), planting conditions (water year, starting from acorns or saplings, weed mats, mulch, density of plantings and other adjacent veg, etc.), establishment and maintenance practices (manual or installed irrigation systems, and irrigation intervals), and the required success criteria (target % survival), the estimated water demands are difficult to predict.¹⁴ However, in order to be reasonably conservative, this WSA assumes that each acre of habitat mitigation will require 1 acre-foot per acre of annual irrigation for a period of 15 years.¹⁵ For instance, if the Proposed Project must mitigate with 10 acres of woodland, the demand would be 10 acre-feet annually. All oak woodland will be established prior to build-out and require no on-going irrigation.

Recreational Lake

The recreational lake is expected to need augmentation water to maintain desired lake elevations. Currently, the lake fills from adjacent groundwater seepage and stormwater runoff. Based on characterizations of this seepage from Proposed Project representatives, the water elevation often lowers during the summer and fall as surface evaporation outpaces seepage. To maintain water level elevations in the 10-acre lake, and estimated 6 to 10 acre-feet per surface acre of the lake will be assumed. For the entire lake, this equates to between 60 and 100 acre-feet. For purposes of the WSA, an assumed annual demand of 85 acre-feet will be used.

Vineyards

The Proposed Project will include approximately 55 acres of vineyards spread throughout the project. These vineyards serve as both an aesthetic feature and a business function – actively producing wine grapes. The majority of the planting is located on lots spread between differing housing types. Vineyards are also used in medians and other ornamental type plantings where appropriate. The use of vineyards in this fashion results in lower water use than fully landscaped medians. The vineyard water use estimates is based on a collection of documents from the University of California – Cooperative Extension combined with input for a local producer and winemaker. Reviewing water use data from *Wine Grape Cost and Return Studies, El Dorado and Amador Counties*, as well as other areas with similar climates and elevations, water demand range from 5 to 12 inches per year for established vines. In the interest of being conservative,

¹⁴ A qualified professional will likely develop the project specific oak management plan. More detailed water use will be available in this plan. Review of information from oak mitigation projects in the area revealed a range of planting types, irrigation methods, and management time frames. Overall, irrigation demands were all low as would be expected for a native species.

¹⁵ A conservative water demand number and a long management window were assumed to provide the Proposed Project applicants flexibility in meeting the oak woodland mitigation requirements.

the 12-inch annual value is used.¹⁶ To account for any additional water demands while establishing the vines, this WSA assumes that twice the water will be needed in the first few years following planting. As shown in **Table 2-3**, the initial demand upon planting (included for the first 5-year increment for each vineyard planning phase) is 2 acre-feet/acre. This value drops to 1 acre-foot/acre for the remainder of the analysis period for a particular planting phase.

Gate Houses at Private Entrances

No usable comparison exists in the EID water use history to represent the demand of a gate house. A gate house consists of a small building with a single bathroom. The average country club employee per shift uses 50 Liters per day, or just over 13.2 gallons.¹⁷ Assuming two employees per shift and 3 shifts per day, the resulting water use comes out to about 0.09 acre-feet per year. To be conservative, the demand used is rounded up to 0.1 acre-feet per year.

Sewer Lift Stations

Lift station demand comes in form of maintenance of the stations. Operational flushing at these lift stations is the primary water use. Based on EID records for such operations, each lift station is assumed to demand 2.5 acre-feet of water annually.

Construction Water

As stated in Section 1, early phases of the Proposed Project will include site grading and infrastructure installation. These and other construction elements will require dust suppression and other incidental water uses. These are estimated to be nominal, and do not continue beyond the construction phases of the Proposed Project. For purposes of identifying incremental water demands, construction water is assumed within this WSA to be 11 acre-feet per year (this is well over 3.5 million gallons – or nearly 900 fill-ups of a 4,000 gallon water truck annually).

Modifications to Reflect Additional Water Use Reductions

Similar to the residential demand factors, the above-developed water demand factors for the non-residential classifications are based on similar existing developments in the El Dorado Hills area. Considerations to reduce these baseline values for conservation factors, however, are not required, since demand factors for many of the landscaped features, such as parks, will not change from the existing values – with the exception of commercial land-uses. The landscape-dominant demand factors are affected primarily by climatic conditions that drive plant evapotranspiration. In other words, an acre of turf at a park will still use the same amount of water in the new parks as the existing parks. Commercial land-uses, however, are adjusted downward slightly to reflect the CAL Green Code and likely modifications to landscape designs (compared to existing establishments) to limit outdoor water use. Schools are kept consistent

¹⁶ The water demand is one dimensional and total demand is dependent on area. For the purposes of this WSA, acres are used for the second dimension. Therefore, one acre-foot of water is multiplied by each acre of vineyard. The result is 1 acre-foot/acre which is used in this documents calculations

¹⁷ Tchobanoglous, George, and Edward Schroeder. *Water Quality*. Menlo Park: Addison Wesley Longman, 1987

with the existing demand factor, since the data is based on the average of several schools and the exact configuration and number of students at the proposed schools is not fully defined. **Table 2-2** summarizes the non-residential demand factors used in this WSA.

Table 2-2 – Summary of Non-Residential Demand Factors

Land Use	Current Factor (af/ac)	Conservation % Applied	Factor Used (af/ac)
Office Park/Commercial	2.00	3%	1.94
Parks	2.77	0%	2.77
Schools	1.43	0%	1.43
ROW Landscaping	3.30	0%	3.30
Open Space	0.00	0%	0.00

2.7 PROPOSED PROJECT WATER DEMAND PROJECTION

Combining the Proposed Project’s land-use details and phasing as summarized in **Table 1-1** and **Table 1-2** with the demand factors presented in **Table 2-1** and **Table 2-2**, the water demands for the project from initiation to build-out are estimated. At completion, the Proposed Project is estimated to need 1,927 acre-feet of water annually (prior to considerations of non-revenue water, described in the next subsection) as shown in **Table 2-3**.

2.7.1 Non-Revenue Water Demands

The demand factors presented earlier in this section represent the demand for water at the customer’s meter for each category. To fully represent the demand on EID’s water resources, non-revenue water also needs to be included. Non-revenue water represents all of the water necessary to deliver to the customer accounts and reflects distribution system leaks, water demands from potentially un-metered uses such as fire protection, hydrant flushing, and unauthorized connections, and inescapable inaccuracies in meter readings.¹⁸ In most instances, the predominant source of non-revenue water is from system leaks – the loss from fittings and connections from EID’s water sources through treatment plants, tanks, pumping plants, major delivery system back-bone pipelines, and community distribution systems. Because a significant portion of the delivery system used to bring water to the Proposed Project already exists, the benefits of new piping within the Proposed Project has limited effect on the overall percentage of non-revenue water necessary to operate the system.

¹⁸ The American Water Works Association and the California Urban Water Conservation Council recognize the inherent non-revenue water that is either lost or mis-accounted in urban treated water distribution systems and suggest purveyors strive for a value of 10% of all delivered water. Obtaining this value is dependent on numerous factors including the age and extent of distribution system infrastructure, meter rehabilitation programs, and how a purveyor accounts for actions such as fire flows and hydrant flushing.

Although EID has an established program for identifying and accounting for most unbilled and other system losses, there are still pipeline leaks, unmetered uses, unauthorized connections, meter inaccuracies, and other losses that are difficult to specifically quantify. Consistent with the District’s methodology for calculating future water meter availability, as defined in the *2012 Water Resources and Service Reliability Report*, non-revenue water is projected at a fixed rate of 13 percent. Non-revenue demand is estimated to add 250 acre-feet per year at build-out to the Proposed Project’s land-use demands, bringing the estimated build-out water demand attributed to the Proposed Project to 2,177 acre-feet annually (see **Table 2-3**).

2.7.2 Recycled Water Demand

A portion of the Proposed Project’s demands (see Figure 1-1) could be met with recycled water provided by EID (see Section 4.3). As previously noted, other than the high-density multi-family units, residential potable demands require about 0.18 acre-feet annually per household. The remaining portion of the unit demand factor for each type of residential lot could be met with recycled water (see **Table 2.1** for unit demand factors). For the high-density residential units, the potable water requirement is lower due to fewer customers per unit on average when compared to other housing types. Using these unit water demand assumptions, coupled with the number of residential units, the Proposed Project could meet approximately 937 acre-feet of the 1,510 acre-feet of residential water demand with recycled water – prior to consideration of non-revenue water demands.

Non-residential components of the Proposed Project could also be met with recycled water, especially the parks, vineyards and lake supplementation. Removing the small potable demands for parks and the limited commercial properties, the Proposed Project could meet 355 acre-feet of the 417 acre-feet of total non-residential demand with recycled water – prior to the consideration of non-revenue water demands. Combined, recycled water could serve approximately 1,292 acre-feet of the Proposed Project’s demand (see **Table 2-4**).

Table 2-4 – Estimated Demand Met with Recycled Water

	Demand (af/yr)		
	Residential	Non-Res	Total
Potable	572	62	635
Recycled	937	355	1,292
Total Demand	1,510	417	1,927

SECTION 3 – OTHER ESTIMATED WATER DEMANDS

3.1 INTRODUCTION

As stated in this excerpt from Water Code Section 10910(b)(3): “[T]he water supply assessment for the project shall include a discussion with regard to whether the public water system’s total projected water supplies available...will meet the projected water demand associated with the proposed project, in addition to the public water system’s existing and planned future uses...”

This section details EID’s other “existing and planned future uses.” For purposes of this WSA, existing and planned future uses are subdivided into the following:

- ◆ **Other Currently Proposed Projects** – in addition to the Proposed Project, El Dorado County (County) is the Lead Agency (pursuant to CEQA) for four additional proposed development projects. As Lead Agency, the County has requested separate WSAs from EID for each of these other projects. Because detailed land-use information is available for three of the four projects and separate WSAs are being developed for these three in parallel to this WSA, each of these three projects have unique water demand estimates that are included in this WSA.¹⁹
- ◆ **All Other Existing and Planned Future Uses** – in addition to the Proposed Project and the Other Currently Proposed Projects, existing customers and anticipated growth in the County must be quantified. The subdivisions of this category are:
 - ◆ **Current Customers and Uses** – using 2012 as a baseline condition, this category reflects the current range of EID’s potable and recycled water customers. Because these customers and uses already exist, keeping them separate from planned future uses allows an analysis to reflect anticipated reductions in use over time as EID continues to implement its urban water conservation programs targeted at many of the existing customers.²⁰
 - ◆ **Adjusted General Plan Update Land Use Growth** – in addition to the identified development projects currently undergoing County CEQA review, the County’s 2004 General Plan Update (GPU) anticipates continued urban growth throughout the EID service area. This growth is accounted for in the EID 2013 *Integrated*

¹⁹ EID understands the fourth project, San Stino, to be undergoing changes to its land-use plans at the time of drafting this WSA. Lacking the details needed to determine water demands similar to the other WSAs currently being completed, the San Stino project is reflected in the next subgroup of demands (see Section 3.3).

²⁰ New customers added to EID’s system will have lower demand factors, as discussed in Section 2, and will be less likely to implement additional conservation or see much reduction when changes are made. For instance, many existing customers may still have 3 gallon per flush toilets or even 1.6 gallon per flush toilets, which when replaced, will likely only use 1.28 gallons. New houses will be constructed, per the CAL Green Code, with 1.28 gallon per flush toilets. EID has had conservation and incentives programs for more than 20 years.

Water Resources Master Plan (2013 IWRMP) and serves as the primary water demand driver into the future. Adjustments to anticipated GPU growth to reflect the “Other Currently Proposed Projects” and other proposed land-use changes, however, must be made. The adjustments discussed under this category include: (1) potential changes in the 2004 General Plan land use designations as identified in Facility Improvement Letters received and analyzed by EID; and (2) the removal of the Proposed Project and other proposed project uses being developed under concurrent WSAs.

- ◆ **Other Authorized Uses** – EID does not anticipate increases above 2012 levels in other authorized potable water uses such as fire flows, meter testing, water quality flushing, and ditch system operations. Demands for this category of water use is removed from the general plan growth and included separately.
- ◆ **Non-Revenue Water** – As discussed in Section 2.7.1, an additional demand is seen by EID to treat and deliver water to all customers. Referred to as non-revenue water, this water demand represents a 13 percent increase added to estimated customer demands. This value represents a long-term average experienced by EID.

3.2 OTHER CURRENTLY PROPOSED PROJECTS

As mentioned in the previous section, El Dorado County is the Lead CEQA Agency for four additional proposed development projects and has requested EID to prepare WSA’s for each development concurrent with this Proposed Project WSA. EID is currently drafting three of these four WSAs.²¹ The estimate of water demand for each WSA follows the same methods used in Section 2 of this WSA, with specific unit demand factors applied to each unique land use element. The other projects are:

- ◆ **Central El Dorado Hills** – located along El Dorado Hills Blvd north of Hwy 50, this projects is a planned infill mixed development with primarily residential units and some commercial space.
- ◆ **Lime Rock Valley Specific Plan** – located adjacent to the Village of Marble Valley, this development is a planned residential community with a variety of lot sizes and housing types.
- ◆ **Dixon Ranch Residential Project** – located northeast of the Proposed Project, this development is a planned residential community with a range of lot sizes and housing types, including a number of “age-restricted” units, accompanied by a community club house, parks, ponds, and trails.

²¹ EID understands that the San Stino development project is undergoing changes to the land-use plans previously submitted to the County. Therefore, EID has not begun the WSA for that project.

Based on the detailed analysis completed in the other WSAs, these “Other Currently Proposed Projects” represent approximately 1,330 acre-feet per year of new demand by 2035. **Table 3-1**, presented later in this section, summarizes the estimated water demands as determined and detailed in the concurrent WSAs for each unique project. The values shown are the estimated customer and use demands and do not include the additional water associated with non-revenue percentages attributable to the treatment and distribution for each project (see Section 3.5).

3.3 ALL OTHER EXISTING AND PLANNED FUTURE USES

In simple terms, this category of use would typically reflect all the other water demands anticipated by EID that are in addition to the Proposed Project. However, because of the unique circumstance that other WSAs are concurrently being drafted by EID, this category must be adjusted to remove those other well-defined water demands. Furthermore, because other potential changes to the 2004 GPU have been brought to EID’s attention, and EID anticipates changes to current customer uses, a more detailed assessment of future demands is warranted. This subsection describes:

- ◆ Current Customers and Uses
- ◆ Adjusted GPU Land Use Growth
- ◆ Other Authorized Uses

3.3.1 Current Customers and Uses

Current customers and uses in the contiguous EID service area provide a baseline from which to assess additional demand from the Proposed Project and other potential planned uses. For purposes of the WSA, the deliveries to current customers in 2012 were used to define this baseline. Based on the 2012 EID *Water Diversion Report*, EID diverted 36,580 acre-feet into its potable water system. In addition to the potable water, EID served 2,404 acre-feet of recycled water to meet customer demands.²² Combined, the current water demand is represented as 38,984 acre-feet. This value includes the non-revenue water (see Section 2.7.1), including system losses, necessary to deliver these supplies from their respective treatment plants to the customer meter. This value also includes 1,269 acre-feet sold to the City of Placerville.²³

Since the WSA uses 2012 as a baseline, the “current” demand varies from that used in the recently adopted 2013 IWRMP, which used the year 2008 for its baseline.²⁴ Given on-going conservation efforts, adoption of new rate structures, and other drivers, EID has seen an overall decrease in the annual customer use since the IWRMP selected its baseline. Therefore the 2012

²² See EID 2013 Water Resources and Reliability Report (Table 14)

²³ See EID Consumption Report: Reporting Year 2012 (Table on p. 7)

²⁴ The IWRMP, adopted by the EID Board in March 2013, began several years ago and at the time used 2008 as a baseline. Since that time, EID’s annual diversions have dropped from a high in 2008 of about 45,000 acre-feet to 35,678, 33,453, and 36,580 in 2010, 2011, and 2012, respectively. Combined with recycled water deliveries, the 2012 demand is lower than that used for the 2013 IWRMP, but greater than 2010 and 2011.

baseline used for this WSA is more representative of the baseline use expected into the future from these existing customers and uses.

A slight adjustment to this baseline is necessary, however, to project it into the future. Although this demand will remain relatively constant since it does not add any new uses (additional uses are discussed in the next subsections), a slight decrease is assumed that reflects on-going implementation of conservation and installation of new water-using fixtures by existing customers. EID's continued leadership in conservation will enable existing customers to retrofit toilets, receive appliance rebates for new household items such as dishwashers, water heaters and clothes washers, and implement irrigation efficiency improvements through various incentives. Additional reductions in existing customer demands will also occur simply as a result of the natural replacement of old fixtures and appliances with lower water-use devices. For purposes of the WSA, EID estimates the reduction in current customer demand will be approximately 2% by 2020 and an additional 1% by 2035. This is consistent with EID's expectations necessary to meet its per-capita water use targets as detailed in the 2010 Urban Water Management Plan.²⁵

3.3.2 Adjusted GPU Land Use Growth

In the 2004 GPU, the County made growth projections using land-use zoning throughout the County. Within the contiguous EID water service area, the GPU land-use zoning correlates to EID defined unit water demand factors. During preparation of the recently adopted 2013 IWRMP, EID used GIS-based land-use designations, combined with the water demand factors, to develop estimated growth in water demand. Absent any changes to the 2004 GPU land-use designations, the 2013 IWRMP demand projections would provide a valid representation of future water needs. However, because several proposed changes to the GPU land-use designations have been submitted – both through the County's formal process, such as is the situation with the Proposed Project and Other Planned Projects, and through an EID process explained below – the 2013 IWRMP demand projections require refinement. The steps to adjust these demands included:

- ◆ Removal of Proposed Project and Other Planned Projects water demands
- ◆ Modifying land-use zoning based on Facility Improvement Letters
- ◆ Determining Growth to Year 2035

Once these steps were completed, the analysis reassessed the water demand using the water demand factors applied in the 2013 IWRMP.

Step 1: Removal of Proposed Project and Other Planned Project Water Demands

The first step in adjusting the water demands was to remove the detailed water demands estimated in this WSA for the Proposed Project and for the Other Planned Projects (see

²⁵ See Section 3 of the 2010 UWMP available here:
<http://www.eid.org/modules/showdocument.aspx?documentid=338>

Section 2 and Section 3.2). This step involved removing the specific acreage and water demand factors from the 2013 IWRMP analysis. The 2004 GPU included land-use zoning for the lands underlying the Proposed Project as well as the Other Planned Projects. In the 2013 IWRMP, water demands were estimated using the existing zoning. Removing these land uses eliminates the potential to double-count the associated acreage when assessing the remaining GPU expected growth.

Step 2: Modifying Land-use Zoning based on FILs

When investigating water service from EID for development projects (e.g. lot splits, land use changes, and new service to existing parcels), existing landowners submit a Facilities Improvement Letter (FIL). This document allows EID to assess whether infrastructure or supplies are available to serve the proposed project. In some instances, the FILs include proposed land-use zoning changes not previously incorporated into EID water demand projections. By using GIS to map the locations of the FILs requesting a change in land-use zoning, EID was able to identify where changes to the 2013 IWRMP demand estimates would occur. About 25 specific FILs were identified as having land-use designation changes. These identified parcels were removed from the prior analysis to eliminate potential double counting of demands.

In a separate analysis, the water demand for this subset of parcels was recalculated using the appropriate water demand factor for the new proposed land-use classification (e.g. water needs for these parcels may have previously been calculated based on very-low density housing, but is requesting a change to higher density housing). Through the analysis, an increased demand of approximately 3,000 acre-feet over the 2013 IWRMP projections was identified.

Step 3: Determining Growth to 2035

The GPU identifies anticipated build-out conditions for the County and, as a subset, for the EID contiguous water service area. Since this WSA assesses water demands in 5-year increments only to 2035 – well short of the anticipated timing of the County’s build-out – the amount of build-out growth occurring by 2035 must be determined. This was done for both the parcels identified with new land-use zoning through the FIL analysis, and for the remaining parcels with original GPU land-use designations.

Because there is little detail about planned development rates for the FIL-related parcels, this WSA assumed that these parcels would have full water demand usage by 2035.²⁶ This is a conservative estimate, since some of these lands may not develop by 2035 or may never

²⁶ This assumption also considers that a landowner would likely only submit a FIL to EID if they are seriously contemplating the development activity. Thus, there is a higher likelihood that these parcels will develop at a faster rate than other generally anticipated growth for the remaining parcels in the GPU.

develop. Thus, the estimated increase in demand of approximately 3,000 acre-feet was assumed to occur by 2035 with the 2013 IWRMP growth rate applied.

For the remaining parcels, growth rates used to determine the degree of development were based on EID's 2013 IWRMP. In the 2013 IWRMP, growth rates for the El Dorado Hills, and Western/Eastern water service areas were identified for specific year-ranges.²⁷ This WSA uses those growth rates for the remaining parcels. Using the 2013 IWRMP growth rates, the analysis determined build-out for the El Dorado and Western/Eastern service areas occurs after 2035.

During this adjustment, special attention was provided to the City of Placerville. The City purchases potable water from EID for distribution to its residents. The 2013 IWRMP projected future water demands for the City based on the City's existing General Plan. This WSA assumes the same rate of growth and build-out demand as the 2013 IWRMP for the City.

Upon completion of these steps, the adjusted demand for the GPU land uses was determined. **Table 3-1** summarizes the anticipated increase in water demand during each 5-year increment as a result of these adjustments to the GPU land-uses.

3.3.3 Other Authorized Uses

In addition to the sale of water to metered customers, EID has a set of water demands it refers to as "Other Authorized Uses." This designation is for the following existing uses:

- ◆ Knolls Reservoir Assessment District
- ◆ Private Fire Services
- ◆ Temporary Water Use Permit
- ◆ Bulk Water Stations - Permanent
- ◆ Bulk Water Stations - Temporary
- ◆ Lift Stations
- ◆ Collection System Flushing
- ◆ Spills, Overflows, and Flushing
- ◆ Clear Creek Aesthetics Flow Maintenance District

Of these, the Clear Creek aesthetic flows comprise over 80 percent of the annual authorized uses. Lift stations and temporary use permits comprise another 10 percent. The current demand of approximately 2,200 acre-feet is already reflected in the "Current Customers and Uses." EID anticipates no growth in these authorized water uses, with the total demand to remain constant at 2,200 acre-feet through 2035.

²⁷ EID Integrated Water Resources Master Plan, adopted March 2013 (Table 9-2).

3.4 NON-REVENUE WATER DEMANDS

The subtotal values in **Table 3-1** represent the demand for water at the customer's meter for each category. To fully represent the demand placed on EID's water resources, non-revenue water also needs to be included. Non-revenue water represents all of the water necessary to deliver to the meter and reflects distribution system leaks, water demands from potentially un-metered uses of fire protection, fire hydrant flushing, and unauthorized connections, and inescapable inaccuracies in meter readings.²⁸ In most instances, the predominant source of non-revenue water is from system losses – the loss from fittings and connections from the District's water sources through treatment plants, tanks, pumping plants, major delivery system back-bone pipelines, and community distribution systems.

Although the District has an established program for identifying and accounting for most unbilled and other system losses, there are still pipeline leaks, unmetered uses, unauthorized connections, meter inaccuracies, and other losses that are difficult to specifically quantify. Consistent with the District's methodology for calculating future water meter availability, as defined in the *2012 Water Resources and Service Reliability Report*, non-revenue water is projected at a fixed rate of 13 percent.

As shown in **Table 3-1**, non-revenue demand for Existing and Planned Future Uses is estimated to be about 7,500 acre-feet per year by 2035.

3.5 ESTIMATED EXISTING AND PLANNED FUTURE USES

Combining the estimated water demand for Other Currently Planned Projects (see Section 3.2 with the All Other Existing and Planned Future Uses demand (Current Customers and Uses plus the Adjusted GPU Land Use values), the total estimated demand during each 5-year increment to 2035 is derived (see subtotal water demand in **Table 3-1**).

²⁸ See footnote 14

Table 3-1 – All Other Existing and Planned Future Uses

Category	Estimated Demand (af/yr)					
	Current	2015	2020	2025	2030	2035
Other Currently Proposed Projects	0	163	696	1,052	1,272	1,332
Current Customers and Uses ¹	38,984	34,154	33,809	33,694	33,579	33,464
Adjusted GPU Land Use ²	0	514	2,853	7,975	14,718	22,830
Subtotal Water Demand	38,984	34,831	37,359	42,721	49,570	57,627
	Current	2015	2020	2025	2030	2035
Non-Revenue Water at 13%	--	4,528	4,857	5,554	6,444	7,491
Total Water Demand	38,984	39,359	42,216	48,275	56,014	65,117

1. The "Current Customers and Uses" demand value includes the "Other Authorized Uses." The Value is greater under the "Current" condition because "Non-Revenue Water" is included in the current year. All other years will have "non-revenue water" added on a separate line. A 3% conservation decrease occurs by 2035.

2. "Adjusted GPU Land Use" reflects changes to the 2004 GPU as determined by FILs submitted to EID. This value also does NOT include the other proposed projects currently undergoing County CEQA review.

3.6 TOTAL ESTIMATED DEMAND

The other existing and planned future water demands described in this section represent the total demands anticipated *in addition to* the water demands of the Proposed Project. Combining the estimated Proposed Project water demands of 2,177 acre-feet annually (see **Table 2-3**) with the estimated Existing and Planned Future water demands of approximately 65,000 acre-feet annually (see **Table 3-1**), a total estimated demand for EID water supplies by 2035 is determined. Estimated existing and planned future water demands, inclusive of non-revenue water needs, for each 5-year increment to 2035 are presented in **Table 3-2**. The estimated demand for EID Water supplies is 67,295 acre-feet annually.

Table 3-2 – Total Estimated Water Demands

Category	Estimated Demand (af/yr)					
	Current	2015	2020	2025	2030	2035
Proposed Project	0	141	721	1,285	1,860	2,177
Existing and Planned Future Uses	38,984	39,359	42,216	48,275	56,014	65,117
Total Water Demand	38,984	39,500	42,937	49,560	57,874	67,295

Of note is that the estimated water demand for 2035 presented in **Table 3-2** fits within the range of total demands presented in Table 9-1 of the 2013 IWRMP (estimated to be between 61,262 acre-feet and 77,315 acre-feet). The primary differences is that the 2013 IWRMP used 2008 as a baseline demand, which is substantially higher than EID has seen in the last several years. This WSA uses 2012 as a baseline. The 2008 value was approximately 45,000 acre-feet, while the 2012 value is 38,984 – or about 39,000 acre-feet. This represents a difference of about 6,000 acre-feet. Starting from a different baseline quantity and year, and then applying the 2013 IWRMP growth rates, results in a different estimated total demand when reaching 2035.

SECTION 4 – WATER SUPPLY CHARACTERIZATION

4.1 INTRODUCTION

This section explains the intended water supply that EID will use to serve the Proposed Project.²⁹ EID will meet the Proposed Project’s water demands by utilizing water assets derived from its existing sources as well as through future asset acquisition efforts with El Dorado County Water Agency. This section details the Proposed Project’s available water supplies and entitlements as well as its planned water supplies and entitlements in both normal water years and dry water years. The Proposed Project exists completely in El Dorado Irrigation District’s contiguous water service area (see **Figure 4-1**) and may be served with both treated water and recycled water.³⁰

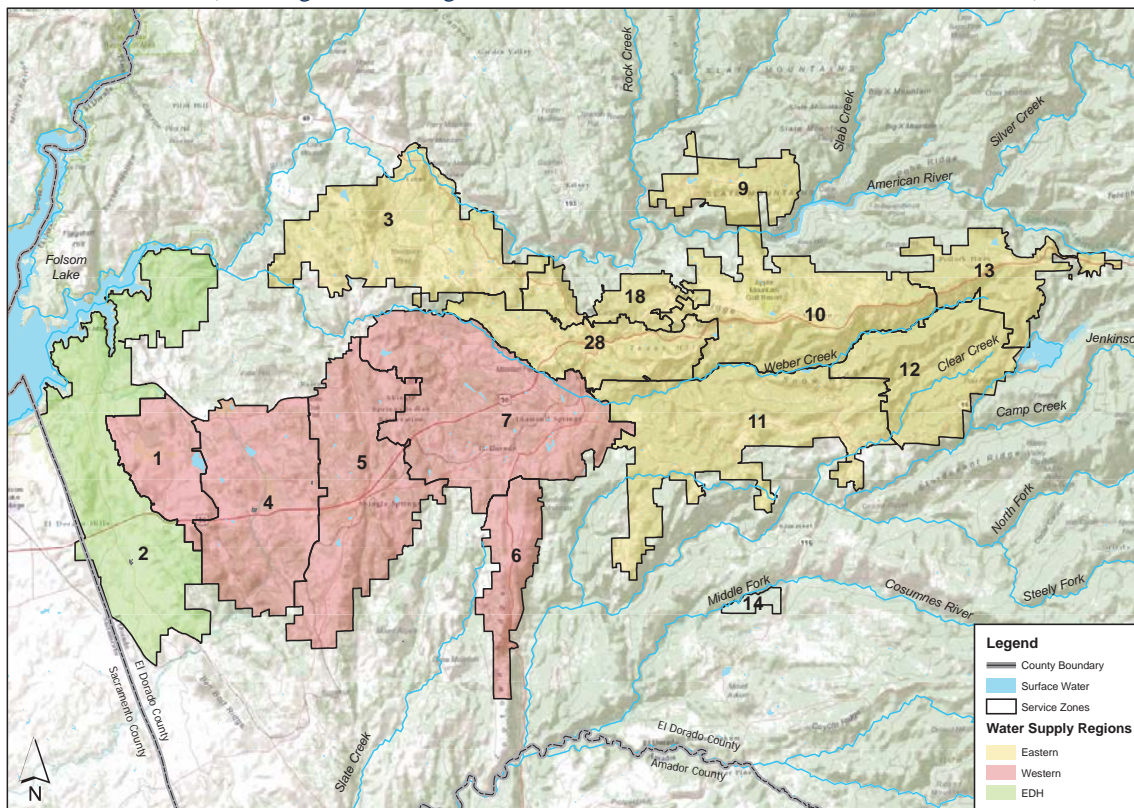

El Dorado Irrigation District maintains two primary interconnected water systems in its contiguous service area: the El Dorado Hills system and the Western/Eastern system, along with a separate recycled water system. The El Dorado Hills water system obtains its primary supplies under rights and entitlements from Folsom Reservoir. The Western/Eastern system derives its supplies from sources under rights and entitlements emanating from further up the American River watershed and the Cosumnes River watershed. The recycled water system serves treated wastewater from the El Dorado Hills wastewater treatment plant and the Deer Creek wastewater treatment plant.

The water assets can be further categorized by the service area they primarily serve and the treatment plant they flow through. Water derived from Folsom Reservoir is delivered to the El Dorado Hills water treatment plant and serves the El Dorado Hills area. Water derived from upstream American River watershed diversions and storage reservoirs generally use the Reservoir 1 Water Treatment Plant while the Cosumnes River diversions use Reservoir A Water Treatment Plant to serve the Western/Eastern area. Water assets from these upstream diversions can be delivered by gravity feed to the El Dorado Hills area, but assets from Folsom Reservoir are not delivered outside the El Dorado Hills area due to infrastructure limitations. The following subsections describe these water supplies and delivery mechanics in more detail.

²⁹ CWC § 10910(d)(1) requires that “The assessment... include an identification of any existing water supply entitlements, water rights, or water service contracts relevant to the identified water supply for the proposed project, and a description of the quantities of water received in prior years by the public water system...under existing water supply entitlements, water rights, or water service contracts. (2) An identification of existing water supply entitlements, water rights, or water service contracts held by the public water system...shall be demonstrated by providing information related to all of the following: (A) Written contracts or other proof of entitlement to an identified water supply. (B) Copies of a capital outlay program for financing the delivery of a water supply that has been adopted by the public water system. (C) Federal, state, and local permits for construction of necessary infrastructure associated with delivering the water supply. (D) Any necessary regulatory approvals that are required in order to be able to convey or deliver the water supply.”

³⁰ EID also has surface water assets that it serves to two non-contiguous areas as well as raw water assets that are used for agricultural purposes. These water assets are irrelevant to the Proposed Project contemplated in this Water Supply Assessment and are, therefore, not analyzed.

Figure 4-1 – El Dorado Irrigation District Service Area
 (from Figure 8-7, Integrated Water Resources Master Plan, EID, March 2013)

4.2 TREATED WATER SUPPLIES

EID’s treated water supplies identified for the Proposed Project are derived from a number of water rights and entitlements as detailed in **Table 4-1**. The maximum available water assets column in **Table 4-1** does not account for other hydrological, technical, regulatory, and contractual limitations that apply to the water assets for normal year and dry year deliveries. These issues are addressed in the other two columns in the table. EID’s water assets available for the Proposed Project include water rights and entitlements that EID currently has in its possession and planned water rights and entitlements that it will control in the future.

4.2.1 Water Rights and Entitlements Description

Generally, EID’s water assets are derived from pre-1914 appropriative water rights, licensed and permitted appropriative water rights, Central Valley Project (CVP) contracts, Warren Act contracts (that allow non-federal water assets to be wheeled through the federal storage and conveyance facilities), and recycled water generated from the effluent treated at the District’s two wastewater treatment plants. The District’s counsel has recently confirmed all of these water rights and entitlements. Pertinent information regarding these water assets is included in **Appendix A** of this document as required by Water Code section 10910(d).

Water for the Proposed Project will be derived from both Folsom Reservoir and upstream American River and Cosumnes River diversions. As shown in **Table 4-1**, the primary water assets for diversion at Folsom Reservoir are: CVP Contract 14-06-200-1375A-LTR1, and License 2184 and several pre-1914 water rights incorporated into Warren Act contract 06-WC-20-3315. EID is seeking to finalize its Warren Act contract for diversions of Permit 21112 at Folsom Reservoir. EID also has additional water assets under the El Dorado – SMUD Cooperation Agreement and a Central Valley Project water entitlement derived from El Dorado County Water Agency’s Fazio water supply. These water assets will be described in **Section 4.2.2**.

Table 4-1 – Water Rights, Entitlements, and Supply Availability

Water Right or Entitlement	Maximum Water Assets Available (Ac-ft)	Normal Year Planned Supply Availability (Ac-ft)	Dry-Year Planned Supply Availability (Ac-ft)
License 2184 and pre-1914 ditch rights including Warren Act Contract 06-WC-20-3315	4,560	4,560	3,000
Licenses 11835 and 11836	33,400	23,000	20,920 ^[A]
CVP Contract 14-06-200-1375A-LTR1	7,550	7,550	5,660
Pre-1914 American River diversion and storage rights	15,080	15,080	15,080
Permit 21112	17,000	17,000	17,000
Subtotal Existing	77,590	67,190	61,660
Central Valley Project Fazio water entitlement (PL 101-514 (1990) Fazio) ^[D]	7,500	7,500	5,625
Applications 5645X12, 5644X02 and partial assignment of Applications 5645, 5644 with El Dorado-SMUD Cooperation Agreement ^[E]	40,000 ^[B]	30,000	5,000 ^[C]
Subtotal Planned	47,500	37,500	10,625
Recycled Water	5,600	5,600	5,600
Total	130,690	110,290	77,885

^[A] This is the modeled safe-yield of this water right during a single dry-year. For planning purposes, the second and third dry years of a three-year dry period are assumed to be 17,000 acre-feet, and 15,500 acre-feet, respectively

^[B] Section 5.1.1 of the El-Dorado SMUD Cooperation Agreement indicates that 40,000 acre-feet of SMUD water will be available after 2025. For conservative Normal Year planning purposes, the District uses 30,000 acre-feet of available supply.

^[C] Available supply is 15,000 acre-feet in a single dry year but in preparing for multiple dry years EID anticipates using only 5,000 acre-feet per year for a three year period.

^[D] Available starting in 2015

^[E] Available starting in 2025

License 2184 and Pre-1914 Water Rights

Water rights associated with Weber Dam, Weber Creek (Farmer’s Free Ditch), Slab Creek (Summerfield Ditch), and Hangtown Creek (Gold Hill Ditch) are available to be diverted at Folsom Reservoir under a long-term Warren Act Contract, with approximately 4,560 acre-feet available each year from these sources. A Warren Act Contract allows the use of federal facilities to take non-CVP water such as these supplies. The 40-year contract commenced on March 1, 2011 and has a maximum net contract amount of 4,560 acre-feet per year. The contract

total also assumes a 15% conveyance loss between the former points of diversion and Folsom Reservoir, which can be adjusted at a later date by mutual agreement without amending the contract. The annual water diversion season is limited to April through November 15 and the water must be used for municipal and industrial purposes in the El Dorado Hills and Cameron Park areas.

Licenses 11835 and 11836

Licenses 11835 and 11836 allow for 33,400 acre-feet of diversion in EID's upstream system in the Cosumnes River watershed. These diversions are stored in Jenkinson Lake, the largest storage reservoir in EID, formed by two earth and rock dams across Sly Park Creek near Pollock Pines with a maximum capacity of 41,033 acre-feet. The dam was constructed as a portion of the United States Bureau of Reclamation (USBR) CVP in 1955. With the transfer of ownership from the USBR of the Sly Park dam and associated lands and facilities in 2003, EID not only operates and maintains the Jenkinson Lake and Sly Park Dam facilities, including recreational aspects, but also holds the water rights. The average annual use from this facility is approximately 23,000 acre-feet, though EID's annual water right is for 33,400 acre-feet of total beneficial use. This water supply is used entirely within EID's contiguous service area. Under average flow conditions, Jenkinson Lake is operated to maintain 14,000 to 18,000 acre-feet of carryover storage each year. The outlet works at Sly Park Dam have a maximum capacity of 125 cfs. Water is released to the Reservoir A Water Treatment Plant for subsequent treatment, transmission, and distribution.

Jenkinson Lake contributes approximately 20,920 acre-feet per year to EID's system firm yield. Over the past five years, EID's annual diversions from Jenkinson Lake have averaged approximately 22,600 acre-feet per year. EID's maximum and minimum diversions from this particular water source during this five-year period were 25,745 and 20,800 acre-feet per year, respectively.

USBR CVP Contract 14-06-200-1375A-LTR1

Surface water from Folsom Reservoir is provided to the El Dorado Hills area. By contract with the USBR for Folsom Reservoir water, EID is entitled to 7,550 acre-feet per year. The contract includes provisions for use in a particular area that generally encompasses the El Dorado Hills and Cameron Park areas. Folsom Reservoir is operated by the USBR as part of the CVP, a multipurpose project that provides flood control, hydroelectricity, drinking water, and water for irrigation.

The El Dorado Hills County Water District entered into a USBR Contract in 1964 for water supply from Folsom Reservoir. The contract had a not-to-exceed limit of 37,600 acre-feet per year. When EID annexed the El Dorado Hills County Water District in 1973, the contract was assigned to EID, and subsequently, in 1979, an amendatory contract replaced the original 1964 contract and reduced the maximum annual supply quantity of Folsom Reservoir water to 6,500

acre-feet per year. In 1983, the USBR increased the maximum annual supply quantity from 6,500 to 7,500 acre-feet per year. EID also annexed and succeeded to a USBR Contract for 50 acre-feet per year to supply the Lakehills area in El Dorado Hills. In 2006, these two contracts were consolidated into a single 40-year USBR Contract with a maximum quantity of 7,550 acre-feet per year.

Pre-1914 South Fork American River and Project 184

EID acquired Project 184 from Pacific Gas and Electric (PG&E) in 1999. Project 184 includes reservoirs and associated dams, 22 miles of canals, a 21 Mw powerhouse, and other ancillary facilities. Prior to the transfer of ownership and water rights, EID held a contract to purchase water from PG&E and its predecessor, Western States Gas and Electric Co. The original water rights claims date back to 1856, with additional claims being filed in the 1860s and 1870s. The water rights for diversions from Echo Lake were established in 1880 in a California Supreme Court decision. Then, in 1918, the California Railroad Commission (predecessor to the California Public Utilities Commission) recognized the use of water from the El Dorado Canal for irrigation and domestic purposes.

The sources of this water supply include natural flows in the South Fork American River and its tributaries, and stored water in Silver, Aloha, Echo, and Caples Lakes. The supply is diverted from the South Fork American River at Kyburz and is conveyed via the El Dorado Canal to the El Dorado Forebay. Some additional water is obtained by diversions into the El Dorado Canal from streams tributary to the South Fork American River. EID takes consumptive use of the water supply at the Main Ditch Intake, located at the El Dorado Forebay. This particular supply contributes 15,080 acre-feet per year to EID's system firm yield.

Water diversions of up to 156 cfs can be made from the South Fork American River at the diversion dam. In addition to these direct diversion rights, EID also has pre-1914 diversion and storage rights associated with portions of the waters stored in Silver Lake, Caples Lake, and Lake Aloha and all of the waters stored in Echo Lake.

El Dorado Forebay is filled by the surface water supply from the Project 184 facilities upstream in the South Fork American River basin and at Echo Lake. EID has a consumptive water entitlement of 15,080 acre-feet per year delivery at the Forebay. The entitlement is a pre-1914 water right, and diversions are made in compliance with the 40-year Federal Energy Regulatory Commission Project 184 operating license issued to EID in October 2006. Because the full entitlement can be provided in all years including the most severe historic single dry year of 1977, this source of water is considered assured, and not subject to shortage from hydrologic droughts.

Permit 21112 and Warren Act Contract

The State Water Resources Control Board (SWRCB) issued EID a water right permit in 2001 for an additional 17,000 acre-feet per year of water supply associated with Project 184 facilities and

power operations to be taken at Folsom Reservoir. This water supply was authorized under Permit 21112 for diversion and consumptive use anywhere within EID's contiguous service area. There are no cutback provisions on this supply.

The El Dorado County Water Agency (EDCWA) and EID applied to the SWRCB to obtain water rights for consumptive use of waters previously stored and released for power generation from Caples, Silver, and Aloha Lakes, as well as certain direct diversions from the South Fork American River, all of which have been used by Project 184 for hydroelectric power generation or instream flows. The EDCWA later assigned all of its rights under this application to EID. The SWRCB granted the right to appropriate 17,000 acre-feet per year of water. Permit 21112 allows EID to make direct diversions from the South Fork American River at Folsom Reservoir; to store in Caples, Silver, and Aloha Lakes; and to divert the water released from storage. The sole approved point of take for consumptive purposes is Folsom Reservoir.

A diversion from Folsom Reservoir requires acquiescence from the USBR and issuance of a Warren Act Contract. EID has diverted water under this right under a temporary urgency basis and the Warren Act Contract is pending.

Recycled Water Supplies

EID produces recycled water at both the El Dorado Hills and Deer Creek wastewater treatment plants which is then used by EID's customers for irrigation of residential landscape and commercial landscape. The availability of recycled water is currently limited to the El Dorado Hills and Cameron Park areas. EID anticipates a 2035 recycled water supply totaling 5,600 acre-feet per year (see Section 4.3 for further details).

4.2.2 Planned Water Supplies

EID has plans to acquire and use two additional water supplies from EDCWA for use within its service area to make available for the Proposed Project – water under the El Dorado-SMUD Cooperation Agreement and water under EDCWA's Fazio CVP supply. This section describes these supplies.

El Dorado-SMUD Cooperation Agreement

As shown in **Table 4-1**, the additional supplies include a grouping of water right applications and assignment of existing water right applications totaling approximately 40,000 acre-feet of water. This supply is being developed by the El Dorado Water and Power Authority (EDWPA). EDWPA is a Joint Powers Authority consisting of El Dorado County, El Dorado County Water Agency and El Dorado Irrigation District (collectively, El Dorado Parties). EDWPA was formed to pursue additional water supplies for the western slope of El Dorado County as determined by the El Dorado County General Plan. This need is identified in the El Dorado County Water Agency Water Resources Development and Management Plan (Water Plan).³¹ The Water Plan is

³¹ http://www.edcgov.us/water/final_water_resources_plan.html

designed to coordinate water resource planning activities within El Dorado County and identifies water supply needs for the western slope of El Dorado County of approximately 34,000 acre-feet per year (AFA) at the 2025 demand level.

In 2005, the El Dorado Parties signed the “El Dorado – SMUD Cooperation Agreement” (included with **Appendix A**), which would help meet the Water Plan’s identified water supply needs. This Agreement requires SMUD to make annual deliveries of up to 30,000 acre-feet of water through 2025 and 40,000 acre-feet thereafter from SMUD’s Upper American River Project (UARP) to the El Dorado Parties. In 2008, EDWPA petitioned the SWRCB for partial assignment of two applications for diversion and storage to obtain water supplies necessary to trigger SMUD’s obligations. A Draft Environmental Impact Report has been prepared in support of the water rights application and was circulated in July 2010. EDWPA is currently in the protest settlement phase and the CEQA process is anticipated to be completed in 2014 with award of water rights shortly thereafter.

The El Dorado-SMUD Cooperation Agreement also obliges SMUD to provide carryover storage and delivery to EID of up to 15,000 acre-feet of drought protection water supplies to be obtained by EDWPA. Based on demand projections, EID anticipates that only 30,000 acre-feet of the 40,000 acre-feet identified in the water right applications and the El Dorado – SMUD Cooperative Agreement will be available to EID in normal years. Moreover, EID has planned that a mere 5,000 acre-feet of the water supply will be available for EID’s uses in each dry year. This number is derived from Appendix H of the El Dorado – SMUD Cooperation Agreement describing deliveries available from carryover storage. Both of these conservative assumptions are shown in **Table 4-1**. EID has planned this supply to be available starting in 2025.

Fazio CVP Supply

EID is also in the final stages of securing 7,500 acre-feet of CVP water supplies in conjunction with EDCWA. In 1990, Congress directed the Secretary of the Interior, through the USBR, to enter into a new CVP Municipal and Industrial (M&I) water service contract with EDCWA for up to 15,000 acre-feet of water annually (Section 206 of P.L. 101-514). The CVP water service contract requires requisite compliance by EDCWA and the USBR with CEQA, NEPA, and ESA statutes.

In 2009, a draft EIS/EIR was released for public review and comment for the CVP M&I water rights contract. In 2010, USBR advised EDCWA that it would take another 5 years before the CVP-Operations Criteria and Plan (OCAP) related litigation would allow the EIS to move forward. As a result, EDCWA made the decision to detach the EIR from the EIS – essentially separating the CEQA and NEPA processes. EDCWA certified the Final EIR and approved the project in January 2011. EDCWA then prepared and submitted to USBR a draft Biological Assessment (BA) in September 2011 and a draft Final EIS in October 2011. USBR submitted

the draft Final EIS to NOAA Fisheries in December 2011. Final EIS completion and contract execution is pending completion of ESA consultation with NOAA Fisheries.

The CVP contract seeks to acquire 15,000 acre-feet of CVP project water, of which at least 7,500 acre-feet would be made available to EID by subcontracts with EDCWA.³² Diversions by EID would occur at its existing intake in Folsom Reservoir, conveyed to the El Dorado Hills Water Treatment Plant, and delivered to a specific place of use location in El Dorado Hills and Cameron Park areas as shown in Figure ES-2 of EDCWA's EIR.

The contract negotiations and environmental compliance efforts are ongoing. These actions allow EID to use this water supply in this WSA as a planned supply that will be available to EID in the future to serve the Proposed Project. The approval of the contract terms as well as finalization of the environmental documents will allow EID to apply the water supplies under this contract entitlement to municipal and industrial beneficial uses. EID has planned this water supply to be available starting in 2015.

4.2.3 Normal Year Water Supply Availability

As shown in **Table 4-1**, EID's total water entitlements under its existing and planned supplies does not equate to the amount of water available in normal years in the future. The normal year water supplies will be described in this section.

Excluding recycled supplies, EID's secured water rights and entitlements available for the Proposed Project total 67,190 acre-feet. As shown in the sufficiency analysis in Section 5, this amount is insufficient to serve EID's future demand incorporating the Proposed Project and all planned future projects. Accordingly, this section assesses both EID's secured supplies and additional planned supplies. EID's water supplies associated with the entire secured and planned water assets totals 110,290 acre-feet per year.

The 67,190 acre-feet of secured supplies include appropriative water right license 2184 and pre-1914 appropriative water rights associated with Slab Creek, Hangtown Creek and Weber Creek. As described above, these rights are collectively combined for conveyance purposes in a Warren Act Contract, No. 06-WC-20-3315, that allows for storage in and diversion from Folsom Reservoir. The total volume is 4,560, net of a negotiated 15% conveyance loss under the terms of the Warren Act contract. For purposes of serving the Proposed Project, EID assumes full diversion at 4,560 in normal years under these water assets.

Appropriative water right licenses 11835 and 11836 are also secured supplies. These supplies can be diverted from several creeks in the Cosumnes River watershed (Camp, Hazel, and Sly

³² Central Valley Project Water Supply Contracts Under Public Law 101-514 (Section 206): Proposed Contract Between the U.S. Bureau of Reclamation and the El Dorado County Water Agency, and Proposed Subcontracts Between the El Dorado County Water Agency and the El Dorado Irrigation District, and Between the El Dorado County Water Agency and the Georgetown Divide Public Utility District Final Environmental Impact Report at ES-1, January 2011.

Park) and are typically stored in Jenkinson Lake. The maximum rate of diversion is 500 cfs for a total possible diversion volume of 33,400. However, due to limitations in storage availability in Jenkinson Lake assessed through OASIS hydrologic modeling, the maximum available normal year supply for the Proposed Project is 23,000 acre-feet.³³ Although EID has diverted as much as 25,745 acre-feet from this reservoir, EID does not anticipate using more than 23,000 acre-feet under this right for its normal year diversions in the future.

Central Valley Project Contract 14-06-200-1375A-LTR1 is a secured supply available for immediate use for the Proposed Project. This CVP contract entitlement requires the USBR to deliver up to 7,550 acre-feet of water from its SWRCB water right permits on the American River to EID.

As described in Section 4.2.1, EID also has a number of pre-1914 appropriative water rights on the American River with storage components in Silver Lake, Lake Aloha, Caples Lake, and Echo Lake. For purposes of this document, these are collectively called the pre-1914 American River water rights.³⁴ The total volume of water available under the pre-1914 American River water rights is 15,080 acre-feet in normal years.

Appropriative water right permit 21112 is a secured supply for purposes of this WSA. Permit 21112 allows EID to divert up to 17,000 acre-feet of water per year from Folsom Reservoir to be used in EID's service area. EID has diverted water under this permit as part of a temporary urgency in 2008. EID must finalize its Warren Act Contract to divert this water at Folsom Reservoir. However, based upon the availability of the supply in Permit 21112, the ability to store the water in Caples, Silver, and Aloha lakes, and the pending conveyance agreement with USBR, the normal-year availability of this supply is 17,000 acre-feet.³⁵

As described in Section 4.2.2, EID's planned water supplies include the CVP Fazio supply of 7,500 acre-feet as authorized under federal law. Once secured, EID should receive normal-year deliveries of the full entitlement just as USBR promises to other CVP M&I contract holders on the American River system. There is no reason to believe that this contract entitlement will be different than other CVP contract entitlements on the American River system.

Last, as described in Section 4.2.2, EID's planned water supplies derived from the EDWPA appropriative water right applications filings and assignments, as well as the El Dorado – SMUD Cooperation Agreement, indicate that EID should receive normal-year water deliveries of 30,000 acre-feet per year starting in 2025 and then as much as 40,000 acre-feet of deliveries thereafter.

³³ 2013 Water Resources Report

³⁴ California Water Code section 10910(d)(2)(A) requires "proof of entitlement" of each individual water right that is combined into this pre-1914 American River water rights grouping. These documents are contained in **Appendix A** of this Water Supply Assessment.

³⁵ EID Urban Water Management Plan 2010 Update, July 2011 at page 4-7 of 22. Follow-up discussion with EID Counsel on water availability on April 23, 2013.

Based on demand projections, the District uses 30,000 acre-feet of normal-year deliveries under these collective applications and the El Dorado-SMUD Cooperation Agreement.

4.2.4 Dry-Year Water Supply Availability

As shown in **Table 4-1**, EID anticipates less water being available in dry years than is otherwise available in normal years as described in Section 4.2.3. Dry-year supplies include supply reductions attributable to hydrologic droughts and regulatory curtailments. The dry-year water supplies are described in this section.

EID's entire normal-year secured and planned water assets total 110,290 acre-feet per year. In dry years, EID's total water assets equal 77,885 acre-feet. Of this total supply, 61,660 acre-feet are secured water assets and 16,225 acre-feet are planned water assets.

As described in Section 4.2.3, the secured water assets include License 2184 and the additional pre-1914 appropriative rights that are included in Warren Act contract 06-WC-20-3315, Licenses 11835 and 11836, CVP Contract 14-06-200-1375A-LTR1, the pre-1914 American River water rights grouping, and Permit 21112. All of these water rights are subject to different regulatory and hydrological restrictions that could result, in some instances, in reduction of the water supplies available under the right or entitlement in dry years.

The water rights contained in the Warren Act Contract 06-WC-20-3315 have some level of regulatory restrictions and hydrological uncertainty. EID's 2010 UWMP indicates that the estimated dry-year yield associated with this water asset is 3,000 acre-feet per year based upon regional hydrologic conditions.³⁶ Accordingly, based upon the presumed hydrologic conditions, the dry-year reliability for this supply in three consecutive dry years is 3,000 acre-feet per year.

Licenses 11835 and 11836 have a full diversion entitlement of 33,400 acre-feet per year. Of that amount, carryover storage in Jenkinson Lake and diminished inflow reduce that entitlement to a normal-year supply of 23,000 acre-feet per year. In dry years, this amount is further reduced based upon hydrologic conditions as well as carryover storage needs for future years from Jenkinson Lake. Accordingly, based upon the OASIS hydrologic modeling report, EID reduces this supply's availability to 20,920 acre-feet in a single dry year. Thus, 20,920 acre-feet per year is used in this WSA as the dry-year safe yield number for a single dry year. To be conservative, EID plans for this supply to be further reduced during year two and again in year three of and three consecutive dry years. This WSA uses 17,000 acre-feet and 15,500 acre-feet as the available supply in year two and year three of a multi-year drought, respectfully.

CVP Contract 14-06-200-1375A-LTR1 has a normal-year entitlement of 7,500 acre-feet per year. The USBR, however, assesses the dry-year supply availability of its CVP M&I contracts

³⁶ EID Urban Water Management Plan 2010 Update, July 2011 at page 4-6 of 22. Follow-up discussion with EID Counsel on water availability on April 23, 2013.

through the CVP M&I Shortage Policy. Based on inflow and storage criteria developed at the joint operations center, USBR can reduce contract water supplies under the CVP M&I Shortage Policy by up to 25% of historic use with various adjustments made for population, use of non-CVP water and extraordinary conservation actions.³⁷ With these adjustments in mind, USBR calculates the reduced CVP M&I delivery essentially based upon the average of the three previous normal years of use under the CVP contract. Under the strictest interpretation of this policy, if the water under the CVP contract was not used, then the dry year water is not available. But, USBR has considered that use of non-CVP supplies in lieu of CVP water use may be used to calculate use under this shortage policy. For purposes of this analysis, however, we have determined that based upon normal growth in demand in EID's service area, EID's customers would utilize the entire contract entitlement in normal years in the future. As such, EID calculates its dry-year reduction for this Proposed Project based upon three years of full use of its contract allocation. Accordingly, the dry year supply under this water contract entitlement is 5,660 acre-feet per year.

EID's pre-1914 American River water rights-grouping has a normal-year reliability of 15,080 acre-feet per year. Based upon the early priority date of these water assets and the storage capability within EID's system associated with these water assets, they are not reduced at all in a single dry year or three consecutive dry years.

Permit 21112 is another secure dry-year water asset. EID's 2010 UWMP states "there are no cutback provisions on this supply."³⁸ As such, the dry year reliability of Permit 21112 is 17,000 acre-feet per year.

As described in Section 4.2.2, EID's planned supplies include the CVP Fazio supply, and the several rights and contract that make up the UARP SMUD water. All of these assets combined have a three consecutive dry year supply reliability of 10,625 acre-feet per year.

The CVP Fazio supply is another CVP M&I contract supply that is subject to the same Municipal and Industrial shortage provisions described above for EID's other CVP contract entitlement. EID's expected portion of the Fazio supply has a normal-year contract allocation of 7,500 acre-feet per year. Assuming under the rules described above that EID is able to use its entire contract entitlement in the future, a 25% reduction from the contract entitlement reduces the delivery by 1,875 acre-feet per year. As such, the single dry year reliability and three consecutive dry year reliability under this contract is 5,625 acre-feet per year.

³⁷ Reclamation has the authority to reduce the supply volumes even further under extreme conditions – Health and Safety criteria – but this sort of supply reduction would only occur in extreme drought and would be offset by reductions in demand in EID's service area, as needed, to maintain basic Health and Safety conditions. The District's drought contingency plans address these situations.

³⁸ This assertion was confirmed in a telephone conversation with the District's Counsel on April 23, 2013.

Last, the UARP SMUD water that is derived from the numerous water right applications and assignments as well as the El Dorado-SMUD Cooperative Agreement indicates that the water available under these components in dry years could be severely curtailed. Appendix H of the Agreement states that annual deliveries can be superseded and deliveries from carryover drought storage can be reduced to as little as 5,000 acre-feet in a declared Critically Dry year if SMUD reservoir storage drops below 100,000 acre-feet (approximately 25%). Out of an abundance of caution, EID anticipates only 5,000 acre-feet of carryover drought-supply water would be available each year over the course of a three-year drought.

4.3 RECYCLED WATER SUPPLIES

EID uses recycled water to meet some current non-potable demands within its service area. EID may expand its development and use of recycled water in the future to meet a portion of the non-potable demands associated with the Proposed Project and other anticipated new demands. EID's current recycled water use is about 2,200 acre-feet per year. This use will expand incrementally over time. By 2035, EID anticipates a supply of 5,600 acre-feet of recycled water per year within its service area.³⁹

EID's recycled water system consists of supply from the El Dorado Hills wastewater treatment plant and the Deer Creek wastewater treatment plant. These treatment plants have an interconnected network of transmission and distribution pipelines, pump stations, storage tanks, pressure reducing stations, and appurtenant facilities located within the communities of El Dorado Hills and Cameron Park.⁴⁰ EID mandates the use of recycled water through Board Policy 7010, wherever economically and physically feasible as determined by the Board, for non-domestic purposes.⁴¹ At this time, non-domestic use includes commercial landscape irrigation, residential or multi-family dual-plumbed landscape irrigation, construction water, and recreational impoundments.

Recycled water availability is an outcome of increased municipal and domestic demand and wastewater production as a byproduct of this demand. In other words, annual recycled water production capabilities are based on the total wastewater flows to the treatment plants. With the population and industrial demands growing in this region, as described in Section 3, the availability of recycled water will increase. EID is taking a conservative view of the growth in recycled water based upon its current production levels, estimated regional population growth, facility expansion identified in its 2013 IWRMP and WWFMP, treated water discharge requirements, and its ability to capture and store recycled water supplies in the future. The total recycled water available for use in 2035 is estimated to be 5,600 acre-feet per year.⁴²

³⁹ EID Integrated Water Resources Master Plan, March 31, 2013

⁴⁰ EID Urban Water Management Plan 2010 Update, July 2011 at page 4-10 of 22.

⁴¹ EID Urban Water Management Plan 2010 Update, July 2011 at page 4-6 of 22.

⁴² EID Integrated Water Resources Master Plan, March 31, 2013 at page 221.

Accordingly, Table 4-2 shows the incremental recycled water assets that would be available over time for the District’s non-potable water uses.

Table 4-2 – Timing of Recycled Water and Quantities

Year	Recycled Water Supply (acre-feet)
Current	2,200
2015	2,400
2020	2,600
2025	3,100
2030	4,200
2035	5,600

4.4 FACILITY COSTS AND FINANCING

EID’s recently completed 2013 IWRMP and WWFMP identify and allocate the future costs of capital expansion and replacement needs, and addresses financing mechanisms for EID’s water assets. These costs and financing mechanisms are hereby incorporated by reference.

The District establishes and periodically updates its Facility Capacity Charges (FCCs) to recover the cost of those portions of existing District facilities that will be used by future customers and to fund needed expansion, or additional capacity, of District facilities to serve new users. The District periodically reviews its FCCs to ensure they accurately reflect the costs of providing service to new customers. Currently the District is updating the FCCs to incorporate projects identified in the adopted 2013 IWRMP. The FCC update is currently under review by the Board and a developer committee, and the District anticipates adoption of the updated FCCs in August 2013.

4.5 REGULATORY APPROVALS AND PERMITS

As described in Section 4.2.2, EID has water assets that require further regulatory approvals, permit compliance, and contract approvals. Each water asset has its own set of regulatory requirements that are assessed in this section.

Appropriative water right Permit 21112 issued by the SWRCB has not been perfected. In order to perfect an appropriative water right, EID must put all of the water assets under that permit to beneficial use. Upon putting the water to beneficial uses and meeting all of the other conditions in the water right permit, EID will be eligible to obtain a water right license for this appropriative water right. Attaining a water right license further fortifies the legitimacy of the water right for EID’s continual use in the future. There is no indication that EID will have difficulty in obtaining a water right license for Permit 21112.

Permit 21112 also requires a Warren Act Contract to be negotiated and approved by the USBR. The Warren Act Contract will allow EID to divert water from Folsom Reservoir for delivery to the El Dorado Hills Water Treatment Plant. Although the District may choose to divert some of the water upstream of Folsom Reservoir through other SWRCB regulatory processes, a Warren Act Contract is essential for any diversions emanating from Folsom Reservoir. EID is currently in negotiations with USBR to obtain a long-term contract. While those negotiations continue, short-term Warren Act Contracts are also obtainable, if needed. There are no foreseeable reasons that these negotiations will not succeed. Both EID's Board of Directors and USBR officials will need to execute the contract once the terms have been drafted, and EID will need to obtain judgment in a judicial action to validate the contract.

The Fazio water supply also has additional regulatory approvals and permits pending. This CVP contract entitlement is authorized by Public Law 101-514. The 15,000 acre-feet of water supply is contemplated to be split equally between Georgetown Divide Public Utilities District and EID. As described in Section 4.2.2, EDCWA is negotiating with USBR on behalf of EID to secure the CVP contract entitlement authorized by this federal statute and finalize the EIS. Accordingly, EID will continue to work with EDCWA and USBR to finalize acquisition of this water supply. Upon completion of the EIS, the EDCWA's designee and USBR officials will need to execute the CVP water supply contract, and EDCWA may need to obtain judgment in a judicial action validating the contract.

The pending water right applications and application assignments before the SWRCB as well as the El Dorado – SMUD Cooperation Agreement constitute the last water supply that is pending further regulatory approvals. As described in Section 4.2.2, EDWPA is awaiting approvals from SWRCB for these water assets. Upon SWRCB approval, EID will obtain 30,000 acre-feet of water under the El Dorado – SMUD Cooperation Agreement.

The SWRCB water right process requires the SWRCB to conduct an internal project review of the applicable technical and hydrological information as well as consider the broader effects on other legal users of water throughout the watershed before issuing a permit. This regulatory process may eventually necessitate a SWRCB hearing where testimony from proponents and opponents of the water right permit is heard and weighed by the SWRCB Board Members before issuing the conditioned permits. Once permits have been issued, then the District must comply with the permit terms and perfect application of the water supplies to beneficial use in order to acquire water right licenses associated with the appropriative water rights.

The El Dorado – SMUD Cooperation Agreement is an agreement among the various parties to cooperate in facilitating the storage and delivery of these water assets to the identified purveyors. As such, through the processing of the water right applications and the furtherance of compliance with the terms of those agreements, the water assets considered there are likely to be available to

EID. The regulatory approvals and permits needed to finalize EID's control over these water assets are moving forward.

4.6 SUPPLY SUMMARY

EID has two broad categories of water assets that are available for the Proposed Project – the secured water assets and planned water assets. Collectively, these supplies total 110,290 acre-feet in normal water years and 77,885 acre-feet in a single dry water year. In year two and year three of a multi-year drought, supplies are further reduced to 73,965 acre-feet and 72,465 acre-feet, respectfully.

As described above, the secured water assets include appropriative water right License 2184 and the accompanying pre-1914 appropriative water rights held under Warren Act Contract 06-WC-20-3315, appropriative water right Licenses 11835 and 11836, CVP Contract 14-060200-1375A-LTR1, the pre-1914 American River storage and diversion appropriative water rights, and Permit 21112. The normal year water supplies available to EID under the secured assets total 67,190 acre-feet per year. In dry years, the water supplies available to EID under the secured assets totals 61,660 acre-feet per year.

The planned water assets, although partially secured, are not yet fully available for EID's use to serve the Proposed Project contemplated in this WSA. As described above, these assets are sufficiently secure to be considered planned supplies for the Proposed Project in 2035. In normal years, the water supplies under these assets total 37,500 acre-feet. In dry years, the water supplies under these assets total 10,625 acre-feet.

Finally, the recycled water assets in both normal and dry years, derived from planned growth and continual indoor water usage regardless of year type, total 5,600 acre-feet in 2035.

SECTION 5 – SUFFICIENCY ANALYSIS

5.1 INTRODUCTION

The analysis detailed in this section provides a basis for determining whether sufficient water supplies exist to meet the estimated water demand of the Proposed Project.⁴³

This section includes:

- Analysis of sufficiency, considering variations in supply and demand characteristics under normal, single-dry and multi-dry hydrologic conditions,
- Analysis conclusions

5.2 SUFFICIENCY ANALYSIS

The sufficiency analysis integrates the water demands detailed in Section 2 and Section 3 with the water supplies characterized in Section 4. The results are presented in **Table 5-1** beginning with “current” conditions (recognized as 2012) and continuing with 5-year increments from 2015 through 2035. While the analysis at various intervals before build-out is important, the most critical projection for the sufficiency analysis occurs in 2035. This analysis assumes that the Proposed Project, along with the other projects simultaneously undergoing a WSA analysis (see Section 3.3), are fully constructed by 2035, and other anticipated growth continues as described in Section 3.4.

Table 5-1 incorporates the Proposed Project water demand projection in **Table 2-3**, assuming the Proposed Project develops as detailed in Section 1, and the estimated water demands for all other existing and planned future uses through 2035 as detailed in **Table 3-2**. **Table 5-1** also presents the available water supplies for the contiguous EID service area during normal, single-dry and multiple-dry years, as detailed in Section 4. The water demands and available supplies in a single dry-year and multiple dry-year condition are discussed in the following subsections.

⁴³ CWC § 10910 (c)(4) provides that “If the city or county is required to comply with this part pursuant to subdivision (b), the water supply assessment for the project shall include a discussion with regard to whether the total projected water supplies, determined to be available by the city or county for the project during normal, single dry, and multiple dry water years during a 20-year projection, will meet the projected water demand associated with the proposed project, in addition to existing and planned future uses, including agricultural and manufacturing uses.”

Table 5-1 – Comparable Analysis of Supply and Demand

Year	Project Water Demand (af/yr)	All Other EID Water Demands (af/yr)	Total Water Demands (af/yr)	Non-Revenue Water @ 13%	Demands with Loss	EID Water Supplies

	1,720	51,432	53,152	6,910	60,061		Year 3	14,285	52,580		66,865	72,465	12,404

5.2.1 Single Dry Year Supply and Demand Conditions

Under this condition, EID would anticipate a variance from the normal-year analysis, including: (1) shortage in full availability of supplies as detailed in **Section 4**, and (2) an increase in water demand. The increase in demand is based on the following:

- Landscape irrigation demands will increase to reflect the generalized earlier start of the landscape irrigation season due to limited rainfall in the single driest year. Since this increase only applies to the outdoor portion of a customer's demand, an adjustment factor of 5 percent is applied to the total normal-year water demand values.
- Historically, during single dry year circumstances, EID does not implement its shortage contingency plan,⁴⁴ since the extent of the dry conditions into future years is unknown. EID follows adopted policies and its 2008 *Drought Preparedness Plan* when implementing any voluntary or mandatory demand reduction measures.

As a result of these factors, the Proposed Project water demand and those of the other existing and planned uses is expected to increase in a single dry year above the demand expected under normal hydrologic circumstances. Additionally, as detailed in Section 4, EID anticipates a decrease in available water supplies. These changes are shown in **Table 5-1**.

5.2.2 Multi-Dry Year Supply and Demand Conditions

When a single dry year expands into a series of dry years, water supply and demand conditions will continue to evolve. Under such a multi-dry year, EID would anticipate many similar conditions that were assumed for the single-dry year, including: (1) shortage in full availability of supplies as detailed in Section 4, and (2) increases in projected demands. However, when entering the second and third year of a sequence of dry-years, EID would implement necessary policies to manage limited water supplies.⁴⁵ Demands over a series of three dry years are adjusted as follows:

- Year 1 – the first year mimics a “single-dry year” condition, where demands increase approximately 5 percent and EID shortage policies are not yet invoked (see Section 5.2.1).
- Year 2 – The demands again mimic a “single-dry year” and would be expected to increase by 5 percent above normal year conditions. However, when recognizing a second dry-year, EID would invoke the first stage of the Drought Preparedness Plan. This stage states: “*The objective of Stage 1 is to initiate public awareness of predicted water shortage conditions, and encourage voluntary water conservation to decrease*”

⁴⁴ See EID Board Policy AR 5011-Water Supply Management Conditions (available at <http://www.eid.org/modules/showdocument.aspx?documentid=2687>).

⁴⁵ See EID Board Policy AR 5011-Water Supply Management Conditions (available at <http://www.eid.org/modules/showdocument.aspx?documentid=2687>).

normal demand up to 15%.”⁴⁶ As part of this stage, EID implements drought water rates among other specified activities to encourage conservation. For purposes of this WSA, the demand reduction achieved under Stage 1 is estimated to be 7 percent of the already higher single dry-year demand.

- Year 3 – Upon entering the third dry year, EID would invoke the second stage of the Drought Preparedness Plan. This stage states: “*The objective of Stage 2 is to increase public understanding of worsening water supply conditions, encourage voluntary water conservation measures, and then if necessary, enforce mandatory conservation measures in order to decrease normal demand up to 30%.*”⁴⁷ Under this Stage, EID increases efforts to reduce demand. For purposes of this WSA, the savings achieved under Stage 2 is estimated to be 15 percent of the already higher single dry-year demand.

As a result of these factors, the Proposed Project water demand and those of the Other Existing and Planned Uses is expected to increase in the first year of a multi dry-year condition above that estimated during normal hydrologic circumstances. In subsequent years, the demand will drop as elements of EID’s Drought Preparedness Plan are implemented. These changes are shown in **Table 5-1**.

5.2.3 Analysis

As shown in **Table 5-1**, the demand and supply are compared under each hydrologic condition for each 5-year increment out to 2035. The resulting “supply surplus” or “supply shortfall” is shown in the final column. Based on the analyses, EID anticipates it will have sufficient water under all hydrologic conditions in each of the 5-year increments through 2035. Notably, the “surplus” supply is lowest during the second year of a multi-dry year condition, since this is the circumstance where demand is only slightly constrained, while supplies are the most constrained. Yet, even under such circumstances, sufficient water should be available.

5.3 SUFFICIENCY ANALYSIS CONCLUSIONS

As detailed in **Section 2**, this WSA estimates water demands for the Proposed Project of 2,177 acre-feet per year at build-out (including non-revenue water demands). The annual water demand estimate for all existing and planned projects in the contiguous EID service area, as detailed in **Section 3**, is approximately 67,300 acre-feet per year by 2035. After accounting for these demand projections for the next twenty years, EID should have sufficient water to meet the demands of the Proposed Project and its other service area demands for at least the next 20 years.

⁴⁶ See EID Board Policy AR 5011.2-Water supply slightly restricted Drought Stage 1 – Voluntary reductions in use (available at <http://www.eid.org/modules/showdocument.aspx?documentid=2687>).

⁴⁷ See EID Board Policy AR 5011.3-Water supply slightly restricted Drought Stage 2 – Voluntary and mandatory reductions (available at <http://www.eid.org/modules/showdocument.aspx?documentid=2687>).

The conclusion that EID should have sufficient water available to meet the needs of the Proposed Project, in addition to the other demands in its service area through 2035, rests on the following set of assumptions:

- ◆ EID, EDCWA, and EDWPA successfully execute the contracts and obtain the water right permit approvals for currently unsecured water supplies discussed in Section 4. Absent these steps, the water supplies currently held by EID and recognized to be diverted under existing contracts and agreements would be insufficient in 2035 to meet the Proposed Project demands along with all other existing and planned future uses.
- ◆ EID will commit to implement Facility Capacity Charges in an amount sufficient to assure the financing is available as appropriate to construct the necessary infrastructure as detailed in the March 2013 EID *Integrated Water Resources Master Plan*.
- ◆ Demand in single-dry years includes an additional 5 percent of demand over the normal year demand during the same time period. This conservative assumption accounts for the likelihood that EID customers will irrigate earlier in the season to account for dry spring conditions. This hypothetical demand augmentation may or may not manifest in dry years, but this conservative assumption further tests the sufficiency of water supplies during dry conditions.
- ◆ The estimated demands include 13 percent to account for non-revenue water losses (e.g. distribution system losses).

The finding of this WSA is that EID should have sufficient water to meet the demands of Proposed Project and its other service area demands for the next 20 years.

MEMORANDUM

To: Shahira Ashkar, ICF International

Date: May 30, 2014

From: Greg Young, Tully & Young

Subject: Water Supply Options to El Dorado Irrigation District's Long-Term Planned Water Supplies for use in the Central El Dorado Hills CEQA Compliance Document

The purpose of this memorandum is to document the water supply options to El Dorado Irrigation District's (hereafter the "EID") long-term planned water supplies as detailed in the Central El Dorado Hills Specific Plans Water Supply Assessment (hereafter "Central EDH WSA") adopted by EID on August 26, 2013. The information and text included in this memorandum can be directly inserted, as best determined by ICF, into the body of the CEQA document that ICF is preparing for the subject project.¹

In *Vineyard Area Citizens for Responsible Growth v. City of Rancho Cordova* (2007) 40 Cal 4th 412 (hereafter *Vineyard*), the California Supreme Court identified specific requirements for an adequate analysis of water supply issues in an Environmental Impact Report (EIR). The court explained that future water supplies identified and analyzed in an EIR must be reasonably likely to prove available. Speculative water sources and unrealistic water allocations do not provide an adequate basis for a public agency's decision-making. The Supreme Court said that when a full analysis of future water supplies for a project leaves some uncertainty regarding the availability of the identified future supplies, the EIR must discuss possible replacement or alternative supply sources. In addition, the EIR must discuss the environmental effects of resorting to those alternative supply sources. The court held that it is not sufficient to address issues relating to future water supplies by simply stating that future development will not go forward in the absence of a sufficient water supply. (*Vineyard* at 431).

¹ Tully & Young must have an opportunity for review and approval of any changes to the information and/or text presented in this memo that may be recommended by ICF in its adaptation of information into the Central El Dorado Hills Specific Plan's CEQA documentation.

The court also recognized that the ultimate question under CEQA “is not whether an EIR establishes a likely source of water, but whether it adequately addresses the reasonably foreseeable impacts of supplying water to the project.” (*Vineyard* at 450). Accordingly, if uncertainties inherent in long-term planning make it impossible to identify the future water sources with certainty, an EIR may satisfy CEQA if it acknowledges the degree of uncertainty involved, discusses the reasonably foreseeable water supply alternatives, and discloses the significant foreseeable environmental effects of each alternative, as well as mitigation measures to minimize each adverse impact. (*Vineyard* at 434).

Accordingly, the *Vineyard* opinion outlined the following general principles governing an EIR’s analysis of water supply issues:

- An adequate environmental impact analysis for a long-range development plan cannot be limited to the water supply for the first stage of development. It must consider supplies necessary for the entire development.
- Future water supplies identified and analyzed in an EIR must be reasonably likely to prove available. Speculative sources and unrealistic paper allocation do not provide an adequate basis for decision making under CEQA.
- When, despite a full analysis, “it is impossible to confidently determine that anticipated future water sources will be available,” CEQA requires some discussion of possible replacement or alternative supply sources, and of the environmental consequences of resorting to those sources. (*Vineyard* at 432)
- An EIR for a land use plan need not demonstrate that the water supply for the project is assured through enforceable agreements with a provider and built or approved treatment and delivery facilities. To interpret CEQA as requiring firm assurances of future water supplies at early stages of the planning process would be inconsistent with the water supply statutes, which call for an assured supply only at the end of the approval process. (*Vineyard* at 432).
- The “ultimate question under CEQA is not whether an EIR establishes a likely source of water, but whether it adequately addresses the reasonably foreseeable impacts of supplying water to the project.” (*Vineyard* at 434)

For the El Dorado County development that is the subject of this analysis, the Central EDH WSA identified a potential water shortfall in very dry years absent planned water supplies (as detailed below). Accordingly, under the guidance of the *Vineyard* decision, the information that follows characterizes alternative water sources for the identified development.

As detailed in Section 4 of the Central EDH WSA and summarized in the Central EDH WSA’s Table 4-1 (included below), the EID water supplies are separated into two classifications: existing and planned. Combined, the Central EDH WSA concluded that these supplies provide sufficient water for the proposed project (see **Figure 1**).

While there is reasonable certainty that all of the existing EID water supplies are available, there is a degree of uncertainty whether the planned Central Valley Project Fazio water entitlement (hereafter the “Fazio supply”), or the supplies anticipated under the El Dorado-SMUD Cooperation Agreement (hereafter the “UARP supply”) will manifest in the quantities or on the schedule currently planned as EID proceeds through regulatory approval and contracting processes.

Therefore, as directed by the *Vineyard* principles outlined previously, an analysis of options that would provide sufficient water for the proposed project is necessary. The following discussion characterizes three water supply options (hereafter “Water Supply Options”) that are viable alternative sources that could reasonably be available to serve the project.

Figure 1 – Project Water Supplies from the Central EDH WSA

Water Right or Entitlement	Maximum Water Assets Available (Ac-ft)	Normal Year Planned Supply Availability (Ac-ft)	Dry-Year Planned Supply Availability (Ac-ft)
License 2184 and pre-1914 ditch rights including Warren Act Contract 06-WC-20-3315	4,560	4,560	3,000
Licenses 11835 and 11836	33,400	23,000	20920 ^[A]
CVP Contract 14-06-200-1375A-LTR1	7,550	7,550	5,660
Pre-1914 American River diversion and storage rights	15,080	15,080	15,080
Permit 21112	17,000	17,000	17,000
Subtotal Existing	77,590	67,190	61,660
Central Valley Project Fazio water entitlement (PL 101-514 (1990) Fazio) ^[D]	7,500	7,500	5,625
Applications 5645X12, 5644X02 and partial assignment of Applications 5645, 5644 with El Dorado-SMUD Cooperation Agreement ^[E]	40,000 ^[B]	30,000	5,000 ^[C]
Subtotal Planned	47,500	37,500	10,625
Recycled Water	5,600	5,600	5,600
Total	130,690	110,290	77,885

^[A] This is the modeled safe-yield of this water right during a single dry-year. For planning purposes, the second and third dry years of a three-year dry period are assumed to be 17,000 acre-feet, and 15,500 acre-feet, respectively

^[B] Section 5.1.1 of the El-Dorado SMUD Cooperation Agreement indicates that 40,000 acre-feet of SMUD water will be available after 2025. For conservative Normal Year planning purposes, the District uses 30,000 acre-feet of available supply.

^[C] Available supply is 15,000 acre-feet in a single dry year but in preparing for multiple dry years EID anticipates using only 5,000 acre-feet per year for a three year period.

^[D] Available starting in 2015

^[E] Available starting in 2025

Quantity of Water to Replace

To understand the quantity each Water Supply Option must provide, an evaluation of the Central EDH WSA’s conclusions about surplus water is necessary. Table 5-1 of the Central EDH WSA summarizes the assessment of supply and demand for the year 2035. As demonstrated in that table, surplus water exists under all hydrologic conditions: normal, single-dry, and multi-dry years. Absent the Fazio and the UARP water supplies, however, the surpluses shown in the Central EDH WSA Table 5-1 are reduced or even become shortfalls under some conditions. **Table 1** presents the surplus as analyzed in the Central EDH WSA and the resulting change when the Fazio and UARP planned water supplies are removed.

Table 1 – Comparison of Surplus/Shortfall Conditions with and without Planned Supplies at Build-out Conditions (2035)

Hydrologic Year Type	Surplus Water (T. 5-1 of WSA) acre-feet/year	Quantity of "Planned Supplies" acre-feet/year		Surplus/(Shortfall) Water w/o "Planned Supplies" acre-feet/year
		Fazio	UARP	
Normal	42,995	7,500	30,000	5,495
Single Dry	7,225	5,625	5,000	(3,400)
Multi dry (Year 1)	7,225			(3,400)
Multi dry (Year 2)	8,251			(2,374)
Multi dry (Year 3)	12,404			1,779

As demonstrated in **Table 1**, at build-out conditions (2035) during a normal year there is still surplus water even absent the planned supplies, and thus no alternative supply is necessary.

However, during single-dry and multi-dry hydrologic conditions, the absence of the “planned supplies” causes a shortfall under several circumstances. The worst-case shortfall occurs during a single-dry hydrologic year – when supplies are curtailed, demands are elevated due to limited rainfall, and temporary demand management efforts are yet to be triggered by EID. Under these hypothetical shortfall conditions, EID would not have sufficient water to serve the proposed project and other existing and planned uses. Thus, as directed by the *Vineyard* decision, an alternative water supply that would provide up to 3,400 acre-feet during a single dry-year must be identified and its impacts assessed.

Water Supply Options

To enable an assessment in the EIR of Water Supply Options, this memorandum characterizes three Water Supply Options that have been developed to meet the 3,400 ac-ft shortfall:

- Option 1 – Construct Alder Reservoir
- Option 2 – Construct recycled water seasonal storage and implement additional conservation

- Option 3 – Participate in regional groundwater banking and exchange programs

Option 1 – Construct Alder Reservoir

Water Supply Option 1 (Option 1) envisions the construction of a new dam and storage reservoir in the Alder Creek watershed. Option 1 would provide more than ample dry-year water supplies to meet the targeted shortfall identified in **Table 1**. A storage facility on Alder Creek has been studied for many years, with the most recent analysis included in EID’s 2013 *Integrated Water Resources Master Plan* (IWRMP). In the IWRMP, construction of the Alder Reservoir is an integral part of the EID recommended water resources plan. The IWRMP is included in this memo by reference.²

As described in the IWRMP:

“[T]he Alder Dam would be a rock-fill dam approximately 143 feet high with a crest length of 800 feet and width of 30 feet at elevation 5,333 feet. The Alder Reservoir would have a capacity of 31,700 ac-ft and capture approximately 23,100 ac-ft of water in an average runoff year from the Alder Creek drainage basin of 18.6 square miles. A new penstock and 10 MW powerhouse would be located near the existing El Dorado Canal allowing water withdrawn from Alder Reservoir to be used for hydroelectric generation and released into the El Dorado Canal downstream of the Alder Creek inverted siphon.”(IWRMP, p. 201)

Figure 2 represents the proposed location of Alder Dam and the resulting footprint of Alder Reservoir. The new reservoir is projected to provide a dry-year safe yield of 11,250 acre-feet.

Water captured and stored during the spring snowmelt runoff period would be released throughout the remaining months at either (1) Jenkinson Lake via the Hazel Creek Tunnel, (2) the Forebay Reservoir, (3) Folsom Reservoir, or (4) a new point of diversion such as the proposed White Rock diversion.

While the estimated safe yield of 11,250 acre-feet is more than three times the quantity necessary for a Water Supply Option, the Alder Reservoir project as currently planned by EID provides a well-documented alternative that has already undergone assessment and is included in the EID Board-adopted IWRMP.

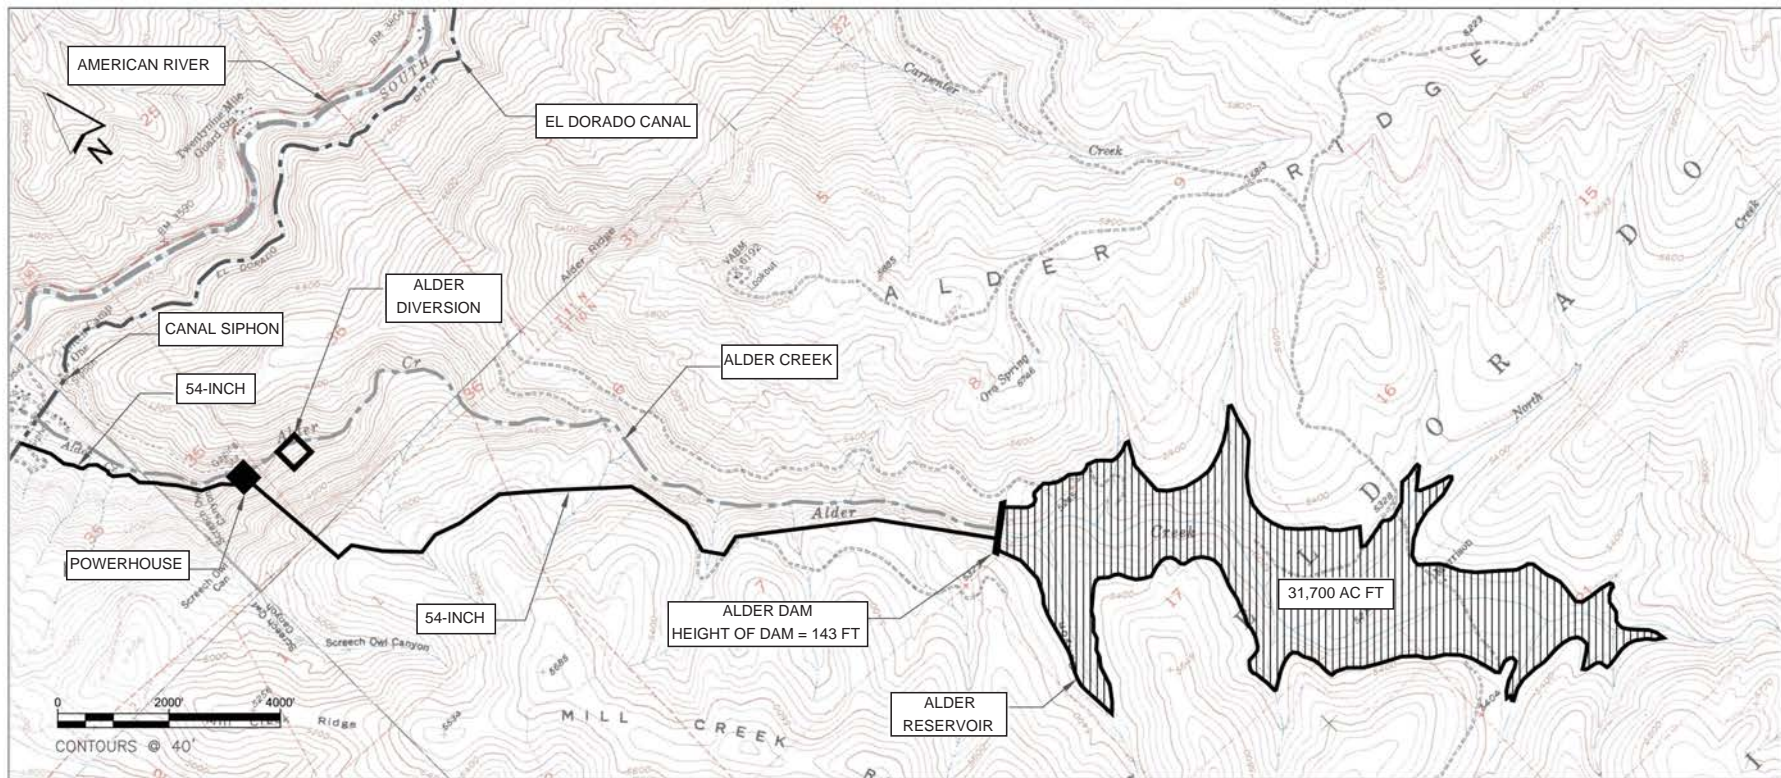

Water Supply Certainty

As detailed in the IWRMP, Alder reservoir would have a capacity of 31,700 acre-feet, capturing about 23,000 acre-feet in an average runoff year from the Alder Creek watershed. The safe yield of the reservoir is estimated to be about 11,250 acre-feet per year. This option provides significantly more water than is necessary to replace the WSA’s planned water supplies. Thus,

² Integrated Water Resource Master Plan, March 2013, accessed on EID’s website via <http://www.eid.org/modules/showdocument.aspx?documentid=3554>

even if the hydrology estimates produced lower runoff quantities, there would still be significantly more water than is required for replacement of the Central EDH WSA's "planned supplies," resulting in a high level of certainty of availability during dry-years.

Figure 2 – Location of Alder Dam and resulting Alder Reservoir
 (source: EID IWRMP, Figure 8-4, p 203)

Source: EID Water Supply Optimization Study, Conceptual Designs and Cost Analyses TM (Domenichelli & Assoc., Inc., 2011)

Option 2 – Construct Recycled Water Seasonal Storage and Implement Additional Conservation

Water Supply Option 2 (Option 2) includes two components: (1) a recycled water seasonal storage reservoir to capture treated wastewater produced by EID that is otherwise in excess of the daily demand for recycled water, and (2) additional water conservation actions implemented by EID and its customers to reduce customer demand and/or reduce delivery system losses.

Seasonal Storage Reservoir

The first component, seasonal storage for recycled water, has been analyzed by EID. In a report published in May of 2011, EID detailed an assessment of potential seasonal storage locations (see *Basis of Design Report - EID Recycled Water Seasonal Storage Reservoir*, May 2011 [hereafter referred to as the “Design Report”]), included as **Attachment 1**.

Of the twenty locations assessed in the Design Report, two locations were determined most suitable for additional analysis (see **Figure 3**). These were:

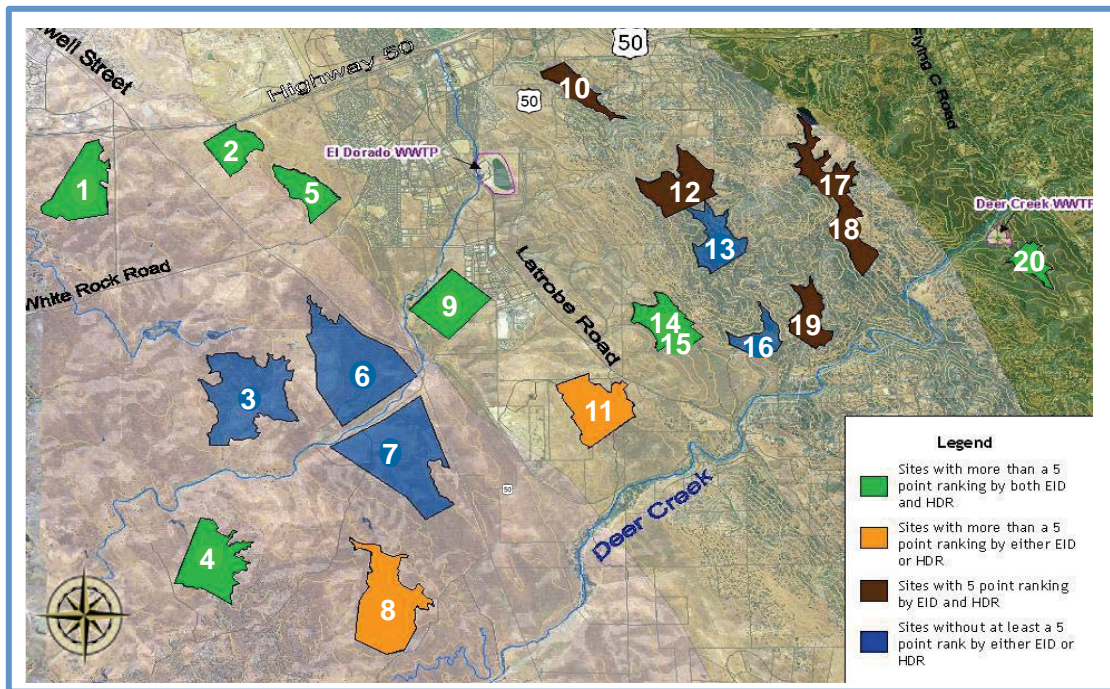

- El Dorado Hills Reservoir - Site 15 located south of the El Dorado Hills Wastewater Treatment Plant
- Deer Creek Reservoir – Site 20 located just south of the Deer Creek Wastewater Treatment Plant

These sites were thoroughly investigated to determine each location’s ability to store 2,500 acre-feet of annual recycled water supply, allowing the supply to shift in time for use during peak summer months when demand otherwise exceeds recycled water production quantities. With the ability to store up to 2,500 acre-feet of recycled water produced during the off-season, EID can expand its water supplies. Currently, and as documented in the Central EDH WSA, EID must augment recycled water supplies with treated water supplies during the year due to the lack of storage. With storage, more recycled water can be used to meet demands, allowing other existing water supplies to be directed to other existing and planned future uses.

Section 4 of the Design Report provides detailed information regarding site location, geology, embankment design, pipeline routing, and other relevant information.

Figure 3 – Sites investigated in the EID Design Report

(source: EID's Basis of Design Report - EID Recycled Water Seasonal Storage Reservoir, May 2011, Figure 3-5, p. 22)

Water Conservation

With availability of 2,500 acre-feet from a recycled water storage reservoir to help meet the 3,400 acre-foot shortfall in dry years, the water conservation component of Option 2 would need to provide an additional 900 acre-feet. This supply may manifest either as additional reduction in EID customer demands, or as a reduction in distribution system losses.

Currently, EID implements a variety of water conservation practices consistent with the best management practices (BMPs) identified in the California Urban Water Conservation Council's (CUWCC) Memorandum of Understanding. These programs are part of EID's on-going operations, and include, but are not limited to: tiered pricing, water meters, leak audits, and public education. EID's Water Efficiency Programs offer numerous options directed towards conserving customer's water uses for commercial, residential, and landscaping purposes.

As demonstrated in Section 3.3 of the Central EDH WSA and summarized in the Central EDH WSA's Table 3-1, the existing EID customers are anticipated to reduce their demands through implementing conservation actions over the analysis period. Specifically, EID anticipates current customer demands will reduce by 2% by 2020 and an additional 1% by 2035. As shown in the Central EDH WSA Table 3-1, these savings are estimated to reduce current customer demands by 690 acre-feet annually.

Under this portion of Option 2, additional conservation actions will target generating an additional 900 acre-feet, slightly more than the conservative estimates of conservation identified in the Central EDH WSA.

Though there may begin to be limits for additional conservation opportunities from existing EID customers, EID also recognizes opportunities to conserve water through improvements to its existing water delivery infrastructure. As detailed in Section 3.4 of the Central EDH WSA, a “non-revenue” component of total water demands represents the system losses, meter inaccuracies, illegal connections, and other factors that help explain the differences between metered customer use and water entering EID’s distribution system. For purposes of the Central EDH WSA, and as a conservative planning tool in other EID water planning efforts, this non-revenue value is assumed to hold constant at 13% of the overall customer demand. The 13% reflects over 4,500 acre-feet of water essentially unaccounted-for in EID’s system under current delivery conditions. With increased customer demands, this value increases to over 7,500 by 2035. By fixing system leaks and addressing other elements of non-revenue demands, water can be recaptured and made available to meet customer demands.

As a routine part of its operations, EID works to identify sources of non-revenue demand, seeking to improve delivery system efficiencies as economically feasible. Though the specific requirements and resulting water savings from addressing overall distribution system losses and inefficiencies are an evolving process, EID has been successful in the past and will continue to do so into the future. As issues are identified, EID evaluates options, assesses costs, and details savings opportunities. As these plans are developed they are assigned a project number, priority level, and moved into EID’s Capital Improvement Plan (CIP) as specific projects.

One example of a water conservation project EID has assessed and included as part of its CIP is the Main Ditch piping project from Forebay Reservoir to the Reservoir 1 Water Treatment Plant. The conservation savings from piping a 3-mile long earthen canal that carries as much as 15,080 acre-feet annually are estimated as high as 1,300 acre-feet per year. In addition to the water savings from this project, public health benefits will also accrue including lower sediment levels in the raw water reaching the treatment plant and greatly reduced risk of contamination. EID has included this project in its latest Board approved CIP and is currently working to secure funding.³ For purposes of Option 2, this particular system loss reduction project is assumed to achieve the additional 900 acre-feet of conservation supply.

In 2004 EID participated in the testing of the new American Water Works Association water audit methodology (AWWA audit) to evaluate the losses from its delivery system. From the AWWA audit, EID recognized it had significantly reduced its water losses over

³ EID 2014-2018 CIP, Project Number 11032

the previous decade, from 28% in 1991 to 13% in 2004. With a decade passing since the AWWA audit, there have been improvements in leak detection technologies as well as growth in the number and experience of contractors specializing in leak detection and repair. As EID continues to improve its distribution system to efficiently meet customer needs, some of the opportunities identified by the 2004 AWWA audit may now be cost effective to investigate, assess and implement.

Along with continued investigation, assessment and implementation of actions to reduce non-revenue demands, EID can expand current rebate programs and other customer-focused water conservation measures. An additional one percent reduction in the demands of current customers, beyond the savings already anticipated in the Central EDH WSA, could reduce demand by another 350 acre-feet annually.

As a conservative assumption, an additional one percent reduction in customer demands through conservation measures and a one percent reduction in the non-revenue demands could produce over 900 acre-feet of water annually. Greater reduction in either category and/or piping the Main Ditch would only increase the savings further.

Water Supply Certainty

Combined, the recycled water seasonal storage reservoir and additional conservation measures could generate at least 3,400 acre-feet needed in dry years. Because the seasonal storage facility would capture and regulate the consistent outflows of EID's wastewater treatment plants, the identified yield is considered to be highly reliable under all hydrologic conditions. Long-term reductions in customer demand and fixes to distribution system inefficiencies also provide a consistent savings regardless of hydrologic conditions. Thus, this Water Supply Option provides a high level of certainty of availability during dry years.

Option 3 – Participate in Regional Groundwater Banking and Exchange Program

Under Water Supply Option 3, EID would coordinate with other regional water purveyors to exchange wet and normal year EID surface water supplies for use of non-EID water supplies in critical dry years. Option 3 could be achieved in partnership with one or more of many water purveyors that share access to the American River. Any opportunity, however, is premised on an agreement among the parties and regulatory approvals to allow EID surface water supplies to be used or stored outside of EID’s existing place of use during normal and wet conditions, and EID’s use of a partner’s American River-related water supplies during dry conditions.

Like the other two options, this Option 3 needs to assure a minimum of 3,400 acre-feet of water is available to EID during a single dry year.

As presented in the Central EDH WSA and summarized in **Table 1**, at build-out during normal and wet years, EID has a surplus of secured (“existing”) water supplies totaling about 5,500 acre-feet annually. All or a portion of this supply is assumed available for delivery to another regional water purveyor to enable the conjunctive use exchange opportunities envisioned under this option. **Table 2** includes a sample 13-year condition illustrating a potential exchange of water among the parties.⁴

Several water purveyors with surface water rights and entitlements on the American River could participate with EID to develop this water supply option.

As envisioned, EID would exchange normal year water for use of a portion of the partner’s surface supplies (e.g., if Sacramento County Water Agency was the partner, the supply exchanged to EID could be SCWA’s dry year CVP contract water supply or other SCWA water rights). In wetter and normal water years, EID would deliver its 5,500 acre-feet surplus to its conjunctive use partner for use in the partner’s service area (e.g. SCWA would deliver the surface water to its customers). In taking EID’s surplus surface water, the partnering agency would forego groundwater use and thus “bank” groundwater supplies as stored water in the underground aquifer. During critical dry years, the partnering agency would rely upon this banked groundwater to meet local needs and allow EID to divert up to 3,400 acre-feet of its surface rights or entitlements at an existing EID facility in Folsom Reservoir or another existing EID diversion and treatment facility.

⁴ The sample period reflects the CA Department of Water Resources’ Sacramento Valley water year index for 2000 through 2012 from Bulletin 120.

Table 2 – Sample exchange of water among parties to facilitate dry-year water supplies for EID

Year	Sample Hydrology (2000-2012)	EID supply "banked" (af/yr)	Other water to EID (af/yr)	Balance
0	above normal	5,500	0	5,500
1	dry	0	3,400	2,100
2	dry	0	2,374	-274
3	above normal	5,500	0	5,226
4	below normal	0	3,400	1,826
5	above normal	5,500	0	7,326
6	wet	5,500	0	12,826
7	dry	0	3,400	9,426
8	critical	0	2,374	7,052
9	dry	0	2,374	4,678
10	below normal	0	2,374	2,304
11	wet	5500	0	7,804
12	below normal	0	3,400	4,404

Notes:

(1) Sample series of water year types is derived from the CA Department of Water Resources Bulletin 120 series for the Sacramento Valley.

(2) In a second dry year, the EID demand for supplemental water is reduced as shown in Table 1

Water Supply Certainty

This Water Supply Option could generate up to 3,400 acre feet of water for diversion by EID in dry years on a reasonably certain basis – given that any conjunctive use partnership would only be established with a purveyor(s) able to reliably provide adequate dry year surface supplies to EID.

Water Supply Option 3, which would exchange groundwater supplies and surface supplies in the Sacramento region, entails concerns related to the long-term reliability of groundwater supplies. In addition, there are also concerns related to the migration of existing groundwater contamination in eastern Sacramento County as a result of additional pumping under this water supply option. However, these and other water banking considerations are actively being investigated as part of regional conjunctive use opportunities.⁵

⁵ For instance, the Sacramento Groundwater Authority has a defined water accounting framework to track groundwater resource that could be available for exchange via “banking” operations. The Sacramento Central Groundwater Authority is also actively investigating conjunctive use opportunities.

MEMORANDUM

To: Rommel (Mel) Pabalinas, Planning Manager
Gina Hamilton, Senior Planner
El Dorado County Planning and Building Department

Cc: Shahira Ashkar, ICF International
Mike Brink, El Dorado Irrigation District

Date: October 07, 2021

From: Greg Young, PE

Subject: Revalidation of previously adopted Water Supply Assessments for the Village of Marble Valley, Lime Rock Valley, and Central El Dorado Hills Specific Plans

On August 26, 2013 El Dorado Irrigation District's (EID or District) Board of Directors approved and adopted Water Supply Assessments (WSA) for three development projects – Village of Marble Valley (VMV), Lime Rock Valley (LRV), and Central El Dorado Hills (CEDH) – hereafter the “Proposed Project(s)” in El Dorado County (County) as a part of each Proposed Project's Specific Plan.¹

These WSAs assessed the availability and sufficiency of EID's water supplies to meet the Proposed Projects' estimated water demands based on the best available information at that time. The District found sufficient water to meet the demands of each Proposed Project, while also considering the demands of each other Proposed Project as well as all of its other service area demands for at least the next 20 years.

The purpose of this memorandum is to re-evaluate whether changes, if any, to (1) the Proposed Projects' land uses, or (2) updates to EID's water supply and demand analysis, would result in modified conclusions of sufficient water as determined in each WSA in 2013. A key document in this re-evaluation is EID's recently updated 2020 Urban Water Management Plan, which was adopted on June 28, 2021.²

¹ The adopted WSAs can be found on the County website here:

https://www.edcgov.us/Government/planning/specific%20plans/ProposedSpecificPlans/Pages/proposed_specific_plans.aspx

² The Final 2020 UWMP can be found on the District website here:

<https://www.eid.org/home/showpublisheddocument/5666/637619651261230000>

Projected Projects' Land Use Description Updates and Water Demand Forecasts

For the 2013 WSAs, specific land uses were provided for each Proposed Project and used to estimate the water demand of each Proposed Project at build-out. Per communications from El Dorado County through its consultant that is preparing updated CEQA documents for the County's consideration, land uses for VMV and LRV have not changed from representations provided in 2013.³

However, CEDH has proposed some minor adjustments. Per the County, the CEDH project has included a variation whereby it may include up to 1,000 residential units if some of the units are age-restricted, but only 737 residential units if no age-restricted units are included.⁴ This proposed variation would change the high density land use from 10 to 14 units per acre for non-age-restricted to 22 units per acre for age-restricted, whereby the non-age restricted scenario would include 324 units, and the age-restricted 587 units. Under both scenarios, 37 residential units would have densities less than 1 unit per acre, 156 residential units would be at approximately 5 units per acre, and 220 units would be at approximately 10 units per acre. For comparison, the 2013 CEDH WSA analyzed 1,028 residential units where 65 units were between 0.5 and 1 acre per unit, 123 residential units would be at 5 to 8 units per acre, and 310 residential units would be at 9 to 12 units per acre, and the remaining 530 residential units would be at 15-24 unit per acre. This potential variation does not result in significant difference in forecast water demand for purposes of evaluating overall water demand.⁵ And, since the total number of units is consistent with that evaluated for CEDH in the 2013 WSA, the land use assumed in the 2013 WSA is still a valid representation of the Proposed Project.

Overall, the land uses concurrently being considered are equivalent to the land uses evaluated for all three Proposed Projects for the 2013 WSAs, and the total number of proposed dwelling units would be the same as analyzed in the previous drafts of the EIR.

While the land uses are essentially equivalent, a forecast water demand made today using the same land uses may result in an actual lower total build-out demand for each Proposed Project than was calculated in the 2013 WSAs. This would be due to current assumptions about residential and non-residential water use that has been driven by continued statutory, regulatory and common-practice considerations. For instance, since 2013, both the statewide mandatory Green Building Standards Code and the statewide Model Water Efficient Landscape Ordinance

³ Email communications from Shahira Ashkar, Managing Director, ICF to Greg Young of Tully & Young on September 15, 2021.

⁴ El Dorado County Staff Report at November 14, 2019 Planning Commission Meeting:

<https://eldorado.legistar.com/View.ashx?M=F&ID=8776221&GUID=F959EE52-F195-4557-AB8B-333C11C66DA1>

⁵ While both of these designations are considered high-density and thus generally have lower occupancy rates, the 587 units of age-restricted versus 324 units not age-restricted would not result in a substantive quantity of additional water use. For instance, 1.8 people in age-restricted at 55 gallons per person per capita day (gpcd) would equate to 65 acre-feet per year for 587 units. For comparison, assuming 2.3 people in non-age-restricted at 55 gpcd would equate to 46 acre-feet per year for 324 units.

(MWELO) have been modified to require more efficient appliances and fixtures and placed further restrictions on residential and non-residential irrigated landscapes. These factors, as well as a continued conservation ethic among water using customers, has resulted in a lowering of EID's per-capita water demand factors compared to those used for the 2013 WSAs.

Therefore, the land uses for the Proposed Projects represented in the 2013 WSAs are consistent with the current land uses, and the water demand forecasts represented in the 2013 WSAs are likely conservatively high.

2020 Urban Water Management Plan Assumptions and Conclusions

EID recently updated its Urban Water Management Plan (UWMP) to comply with statutory requirements.⁶ A primary driver of an UWMP is for an urban water supplier to assess its water service reliability for at least the next 20 years under water supply conditions assumed for hydrologic conditions in normal and single dry years as well as for droughts lasting five years. To make this assessment requires a detailed characterization of an urban suppliers water supply and customer water use conditions well into the future – including recognizing all potential population growth.

Land use and population growth projections in the EID service area were thoroughly analyzed in Chapter 2 of the 2020 UWMP to provide the foundation for estimating customer water demands through the UWMP's planning period of 2045. This demand forecast is the basis for determining water service reliability conclusions.

As detailed in Chapter 2 of the UWMP, expected housing growth was guided by a study commissioned by El Dorado County in 2020 to update housing and job projections to aid with various transportation studies and General Plan refinements. This effort developed growth projections using two categories⁷:

1. Facility Improvement Letters (FILs) – this designation reflects all development projects known to the District at a particular point in time that have formally submitted an initial request for service to EID. A full list of current FILs is available from the District.
2. Future Beyond FILs – this designation reflects additional development beyond the current FILs on existing parcels within Zone 1, 2 and 4 that are greater than 10 acres and are not otherwise designated for any other use.

⁶ California Water Code Section 10610 et seq. require an urban water supplier such as EID to prepare and adopt and UWMP every 5 years. The current cycle required EID to adopt its UWMP and submit it to the California Department of Water Resource by July 1, 2021.

⁷ Population and Land Use analysis in the EID service area begins on page 2-10 in the [2020 UWMP](#).

The analysis projected total Equivalent Dwelling Units (EDUs) expected within the County, where the EDU value represents the number of residential “dwelling units” that each project would reflect regardless of whether the project includes residential or non-residential land uses. This growth was used to determine estimated number of new connections. The connection forecast is used to estimate future water use, as detailed in Chapter 4 of the UWMP.⁸

The VMV, LRV, and CEDH projects were specifically incorporated into the 2020 UWMP using the same EDU representations in the 2013 WSAs.⁹ The 2020 UWMP states:

*“...it is acknowledged by EID that the future water needs of these developments, should they occur within the planning horizon, have been included in the representations of water service reliability detailed in Chapter 5” of the UWMP.*¹⁰

As required by the California Water Code, EID addressed the reliability of their water supplies to meet demands during average, single dry, and five consecutive dry year conditions, detailing the analysis and results in Chapter 5 of the 2020 UWMP. Importantly, EID concluded it has sufficient water assets to meet its short-term and long-term needs in average, single dry, and five consecutive dry year conditions.¹¹ As stated in the UWMP Water Supply Reliability Summary on page 5-5:

“The District’s water supply portfolio is capable of meeting the water uses in its service area in normal, single dry, and five consecutive dry years from 2020 through 2045.”

Considering the Proposed Projects were explicitly included in the 2020 UWMP, and EID determined it has reliable and sufficient water supplies, the determination of sufficiency extends to the consideration of each Proposed Project. This extension is also supported by statute whereby as part of the requirements for a WSA, the California Water Codes states: *“If the projected water demand associated with the proposed project was accounted for in the most recently adopted urban water management plan, the public water system may incorporate the requested information from the urban water management plan in preparing the elements of the assessment required to comply with subdivisions (d), (e), (f), and (g).”*¹²

In other words, the 2020 UWMP’s recent determination provides the equivalent of the findings of the 2013 WSAs that evaluated sufficiency where the Proposed Projects were not previously included in EID’s 2010 UWMP.

⁸ Customer water use forecast is on Section 4.4.3 and begins on page 4-15 in the [2020 UWMP](#).

⁹ Table 2-5: Summary of Known Large Development Projects in the [2020 UWMP](#).

¹⁰ UWMP at p. 2-14.

¹¹ EID Water system reliability is discussed in Chapter 5 of the 2020 UWMP. Tables 5-2 and 5-3 show supply, demand and surplus water data.

¹² California Water Code Section 10910(c)(2)

Conclusion

As demonstrated in this memorandum and supporting references, the Proposed Projects' land uses have not changed and therefore estimated water use demands would not exceed quantities forecast in the WSAs which were adopted by EID in August of 2013. The 2020 UWMP incorporated these projects specifically into its water supply reliability forecasting and came to the same conclusion as the 2013 WSAs that there is sufficient water service reliability to meet all demands at least 20 years into the future.

Moreover, projected demand could reasonably be determined to be less for the Proposed Projects as calculated in the 2013 WSAs since additional regulations would likely result in a lower demand estimate for the same projects due to more stringent MWELO and residential GPCD estimates.

In summary:

- The original WSAs found water availability and sufficiency for the Proposed Projects through 2035.
- The Proposed Projects are recognized in EID's 2020 UWMP as part of planned future customer demands.
- EID's 2020 UWMP concludes sufficient water supplies for all current and planned future customers through 2045 during normal, single-dry and droughts lasting 5 years.

Therefore, EID's conclusions of water availability and sufficiency to meet the Proposed Projects' estimated water demands as articulated in the 2013 WSAs are still valid, and the 2020 UWMP provides necessary concurrence of these prior conclusions.

CEQA Guidelines Appendix F: Energy Conservation

APPENDIX F: ENERGY CONSERVATION

I. Introduction

The goal of conserving energy implies the wise and efficient use of energy. The means of achieving this goal include:

- (1) decreasing overall per capita energy consumption,
- (2) decreasing reliance on fossil fuels such as coal, natural gas and oil, and
- (3) increasing reliance on renewable energy sources.

In order to assure that energy implications are considered in project decisions, the California Environmental Quality Act requires that EIRs include a discussion of the potential energy impacts of proposed projects, with particular emphasis on avoiding or reducing inefficient, wasteful and unnecessary consumption of energy (see Public Resources Code section 21100(b)(3)). Energy conservation implies that a project's cost effectiveness be reviewed not only in dollars, but also in terms of energy requirements. For many projects, cost effectiveness may be determined more by energy efficiency than by initial dollar costs. A lead agency may consider the extent to which an energy source serving the project has already undergone environmental review that adequately analyzed and mitigated the effects of energy production.

II. EIR Contents

Potentially significant energy implications of a project shall be considered in an EIR to the extent relevant and applicable to the project. The following list of energy impact possibilities and potential conservation measures is designed to assist in the preparation of an EIR. In many instances specific items may not apply or additional items may be needed. Where items listed below are applicable or relevant to the project, they should be considered in the EIR.

- A. Project Description may include the following items:
 1. Energy consuming equipment and processes which will be used during construction, operation and/or removal of the project. If appropriate, this discussion should consider the energy intensiveness of materials and equipment required for the project.
 2. Total energy requirements of the project by fuel type and end use.
 3. Energy conservation equipment and design features.
 4. Identification of energy supplies that would serve the project.
 5. Total estimated daily vehicle trips to be generated by the project and the additional energy consumed per trip by mode.
- B. Environmental Setting may include existing energy supplies and energy use patterns in the region and locality.
- C. Environmental Impacts may include:
 1. The project's energy requirements and its energy use efficiencies by amount and fuel type for each stage of the project including construction, operation, maintenance and/or removal. If appropriate, the energy intensiveness of materials maybe discussed.
 2. The effects of the project on local and regional energy supplies and on requirements for additional capacity.
 3. The effects of the project on peak and base period demands for electricity and other forms of energy.
 4. The degree to which the project complies with existing energy standards.
 5. The effects of the project on energy resources.

6. The project's projected transportation energy use requirements and its overall use of efficient transportation alternatives.
- D. Mitigation Measures may include:
 1. Potential measures to reduce wasteful, inefficient and unnecessary consumption of energy during construction, operation, maintenance and/or removal. The discussion should explain why certain measures were incorporated in the project and why other measures were dismissed.
 2. The potential of siting, orientation, and design to minimize energy consumption, including transportation energy, increase water conservation and reduce solid waste.
 3. The potential for reducing peak energy demand.
 4. Alternate fuels (particularly renewable ones) or energy systems.
 5. Energy conservation which could result from recycling efforts.
- E. Alternatives should be compared in terms of overall energy consumption and in terms of reducing wasteful, inefficient and unnecessary consumption of energy.
- F. Unavoidable Adverse Effects may include wasteful, inefficient and unnecessary consumption of energy during the project construction, operation, maintenance and/or removal that cannot be feasibly mitigated.
- G. Irreversible Commitment of Resources may include a discussion of how the project preempts future energy development or future energy conservation.
- H. Short-Term Gains versus Long-Term Impacts can be compared by calculating the project's energy costs over the project's lifetime.
- I. Growth Inducing Effects may include the estimated energy consumption of growth induced by the project.

Note: Authority cited: Sections 21083 and 21087, Public Resources Code. Reference: Sections 21000-21176. Public Resources Code.

Revised 2009

SUMMARY OF SPECIFIC PLAN POLICIES AFFECTING ENERGY

Appendix K-2

This page is intentionally blank.

C.21 AIR QUALITY AND PUBLIC HEALTH

- 9.51 Installation of open-hearth wood-burning fireplaces shall be prohibited in favor of more energy-efficient and less polluting heating devices using cleaner burning fuels, such as natural gas. All fireplaces and stoves shall be [a direct-vent, sealed combustion type](#) ~~natural gas fired~~.

C.32 CIRCULATION

- 4.1 The Plan Area must include choices among methods of transportation, including roadways, bikeways, and pedestrian ways that are well-connected for a walkable community.
- 4.2 Design the local roadways in the Plan Area as internal systems [with two points of access](#) that do not connect to existing roadways in neighboring subdivisions, unless required for Emergency Vehicle Access (EVA).
- 4.5 Development of the Plan Area shall comply with General Plan Policies TC-Xa through TC-Xi (Measure Y [and E](#)) [as stated in the County's General Plan, as applicable](#).

C.65 ENERGY EFFICIENCY

- 9.11 All buildings shall exceed energy efficiency standards in Title 24, Part 6 of the 2008 California Building Standards Code by a minimum of 15 percent, [or achieve the then-current Building Standards Code by a minimum of 5 percent](#), according to the performance method prescribed in the code (CALGreen Residential: A4.203.1, Nonresidential: A5.203.1; CAPCOA BE-1).
- 9.12 All buildings should, if feasible, incorporate site design measures that reduce heating and cooling needs by orienting buildings on the site to reduce heat loss and gain, depending on the time of day and season of the year.
- 9.13 Cool roofing materials shall be encouraged in both residential and nonresidential buildings, consistent with CalGreen Tier 1 voluntary measures (CALGreen A4.106.5 for Residential, A5.106.11.2 for Nonresidential).
- 9.14 All buildings shall be designed to incorporate the use of high quality, energy-efficient glazing to reduce heat loss and gain.

Policy #	Policy
9.15	All buildings shall include programmable thermostats, home energy management systems, or other similar technologies (CAPCOA BE-2).
9.16	Appliances and any applicable equipment installed prior to occupancy shall be EnergyStar certified, including residential appliances and HVAC systems, nonresidential appliances, office equipment, HVAC, and lighting control systems (CAPCOA BE-4).
9.17	Any covenants, conditions, and restrictions shall allow for the temporary use of clothes lines, drying racks, or similar temporary structures, in order to encourage natural air-drying of laundry and conservation of energy.
9.18	The use of vegetative or man-made shading devices for east-, south-, and west-facing walls with windows shall be encouraged in order to reduce heat gain. Where feasible, wall surface materials shall be minimum SRI 25 (aged), for 75 percent of opaque wall areas (CALGreen A5.106.7).
9.19	All new construction shall obtain third-party commissioning and verification prior to occupancy to ensure that all building systems and components are planned, designed, installed, tested, and operated and maintained to meet the owner’s project requirements (CALGreen 5.410.2 for commercial, A4.207.2 for residential; CAPCOA BE-3).
9.20	Lighting in publicly- or commonly-accessed outdoor areas in all Village Residential - Medium, Village Residential - High, Office Park, Commercial, and Public Facilities land use designations shall both minimize energy use and protect dark-sky conditions through the installation of high-efficiency LED or similar lighting with automatic, dimmable controls (CAPCOA LE-1; LE-2).
9.21	Public street-lighting shall be high-efficiency LED (light emitting diode) or incorporate similar technologies, and be designed with automatic, dimmable controls to both minimize energy use and protect dark-sky conditions, as allowed by the local public agency (CAPCOA LE-1).
9.22	Commercial, residential, and public buildings shall be designed to allow for the installation of renewable energy systems including active solar, wind, or other emerging technologies, and shall comply with the following standards: <ul style="list-style-type: none"> ▪ All buildings shall, at a minimum, be prewired for future solar photovoltaic (PV) system installation. Conduit shall be installed from the building roof or eave to a location within the building identified as suitable for future installation of a charge controller (regulator) and inverter (CALGreen A5.211.4); ▪ Where applicable, rooftop PV arrays or solar water heating systems (SWHS) shall be installed in accordance with the State Fire Marshal safety regulations and guidelines; ▪ Standard rooftop mechanical equipment shall be located in a manner that does not preclude the installation of solar panels;

Policy #	Policy
	<ul style="list-style-type: none"> ▪ Alternative energy mechanical equipment and accessories installed on the roof of a building shall be integrated with roofing materials and/or blend with the structure’s architectural form, if feasible; and ▪ Any covenants, conditions, and restrictions shall allow for the installation of appropriate solar energy collection systems or other architectural features to collect, store, or utilize renewable energy on-site, provided that the systems comply with design guidelines and height limits established in the Specific Plan development standards and applicable provisions of the County Code.
9.23	Solar water heating systems, radiant heating systems, or similar types of energy efficient technologies, shall be required in commercial and multi-family buildings, and encouraged in single-family homes and swimming pools, where applicable.

C.109 LAND USE

3.2	Establish new residential uses in a manner that blends densities with existing subdivisions and locate multi-family sites in proximity to existing services or public transit opportunities to minimize automobile use.
9.1	Minimum off-street parking requirements shall be flexible where shared parking arrangements, on-street parking, car-sharing, or other applicable measures or programs lead to reduced peak parking demand (California Air Pollution Control Officers Association (CAPCOA) PDT-1; CALGreen A5106.6 Parking Capacity).
9.2	Short term and long term bicycle parking and support facilities shall be provided in all Village Residential - Medium, Village Residential - High, Office Park, Commercial, and Public Facilities designations, in accordance with CALGreen Nonresidential Tier 1 Voluntary Measures (see CALGreen A5 106.4; CAPCOA SDT-6 and 7).
9.3	Off-street parking in all Village Residential - Medium, Village Residential - High, Office Park, Commercial, and Public Facilities land use designations shall include a minimum number of dedicated public parking spaces for Low-Emitting and Fuel-Efficient Vehicles ¹ , in accordance with CALGreen Nonresidential Tier 1 Voluntary Measures (see CALGreen A5.106.5.1 for specific standards).
9.4	Off-street parking in all Village Residential - Medium, Village Residential - High, Office Park, Commercial, and Public Facilities designations shall provide some dedicated parking for plug-in electric vehicles (PEVs) and install minimum Level 2 PEV charging stations in each dedicated PEV parking space, in accordance with CALGreen Nonresidential Tier 1 Voluntary Measures (see CALGreen A5.106.5.3 for specific standards; CAPCOA SDT-8).

¹ See CALGreen Section 5.102 for full definition of Low-Emitting and Fuel Efficient Vehicles.

Policy #	Policy
9.5	Off-street parking in private garages or other dedicated enclosed off-street parking spaces in all Village Residential - Low and Village Residential - Medium designations are encouraged to be pre-wired for future installation of minimum Level 2 PEV charging stations, in accordance with Section 406.7 of the California Building Code.
9.6	Electrical outlets shall be provided along the front and rear exterior walls in all Residential designations to allow for the use of electric landscape maintenance tools (CAPCOA A-3).
9.7	The use of “cool pavement” materials will be encouraged, where feasible and subject to the approval of the local agency, in the designs and specifications for all paved surfaces, including, but not limited to, sidewalks, driveways, parking lots, and streets; thereby reducing surface temperatures and radiant heat from paved surfaces. Cool pavements include those meeting Solar Reflectance Index (SRI) values of 29 or greater (LEED-ND GIB Credit 9: Heat Island Reduction).
9.8	Trees shall be interspersed throughout all parking lots so that in fifteen (15) years, fifty (50) percent of the parking lot will be in shade at high noon. At planting, trees shall be equivalent to a 15 gallon container or larger. Fire access roadways in parking areas will have a required fifteen feet vertical clearance.
9.9	Solar canopies, intended to both shade parking lots and generate renewable energy, shall be encouraged.

C.121 MOBILITY AND CONNECTIVITY

4.6	Develop a cohesive pedestrian network of public sidewalks and street crossings that make walking a convenient and safe way to travel. Provide direct links between streets and major destinations within the Plan Area, such as future transit stops, schools, parks, and shopping centers, when feasible.
9.10	The Master Owners’ Association (MOA) shall work with area residents, businesses, and other interested parties, such as the Highway 50 Corridor TMA, to create or participate in a transportation management association (TMA), and prepare and implement a multi-strategy Transportation Management Plan (TMP) for the Plan Area. The TMP shall incorporate transportation demand management strategies as described in Section 9.4.2 (Transportation -Demand Management), and will be managed through the TMA, as administered by the MOA or other similar organizations (CAPCOA TRT-1 through TRT-15).

C.165 POTABLE WATER, RECYCLED WATER, WASTEWATER, AND DRY UTILITIES

- 8.1 Design and construct the necessary potable water, recycled water for irrigation (if economically and physically feasible), wastewater, and storm water infrastructure required to serve the Plan Area. All infrastructure improvements shall follow the conceptual Water, Wastewater, Recycled Water, and Storm Water Master Plans, and shall be constructed in sequence to meet the immediate needs of individual development projects.
- 8.2 Final master utility plans for water, recycled water (if economically and physically feasible), and wastewater shall be reviewed and approved by EID in a Facility Plan Report (FPR) at the improvement plan stage.
- 8.3 Final master utility plans for dry utilities (gas, electric, telephone, and cable) shall be reviewed and approved by the appropriate public utility purveyor in joint trench designs and composite plans at improvement plan stage.

C.176 PUBLIC SERVICES *(Fire Protection, Solid Waste Collection, Schools, and Parks)*

- 7.285 All construction projects shall be consistent with the County’s Construction and Demolition Debris Diversion Ordinance to reuse or recycle a minimum of 65 percent (consistent with Policy 9.29 of this Specific Plan) of construction and demolition debris.
- 7.296 Green waste service for residential units shall be provided to the maximum extent feasible, and as determined by the El Dorado Hills CSD’s Multi-Cart program and franchise agreement with El Dorado Disposal.

C.187 SHCOOLS, PARKS, AND RECREATION

- 3.10 Provide private neighborhood parks and public village parks at an overall minimum standard of 5 acres per 1,000 residents, linking them to residential areas and activity centers through a network of sidewalks, bike paths, and trails.
- 3.11 All multi-family and high-density residential sites are encouraged to incorporate on-site recreational amenities for their residents.
- 5.16 Connect the land uses in the Central District with walking trails, sidewalks, and bike paths to reduce automobile trips and facilitate healthy lifestyles.
- 7.4 Link schools to the pedestrian trail and bicycle path network to encourage non-motorized transportation.
- ~~7.76.1~~ To promote walking and cycling, village and neighborhood parks shall be connected to the pedestrian and bicycle network.

Policy #	Policy
7.8 6.2	Locate neighborhood parks reasonably central to the neighborhoods they are intended to serve.
7.13 6.7	Village parks shall be located adjacent to public arterial or collector roadways, <u>and where feasible, adjacent to public schools to promote joint-use facilities.</u>
7.17 6.12	Master plans shall be prepared for all public village parks and shall include a lighting plan, if applicable.
6.13 7.18	All park lighting fixtures shall be shielded and energy efficient.
6.14 7.19	Design and landscape parks to provide shade, easy maintenance, and water efficiency.
C.2019	TRAFFIC CALMING
4.9	Reduce vehicular speed by designing local roads with narrower traffic lanes, roundabouts, well-marked pedestrian crossings, bulb-outs, or median treatments to improve pedestrian travel and comfort. <u>Any such traffic calming device must be reviewed and approved by the local fire protection district.</u>
C.210	WASTE REDUCTION AND RECYCLING
9.24	Residential construction shall incorporate foundation systems, which result in not less than a 20 percent reduction in cement use in the foundation mix design through use of fly ash, slag, silica fume, or rice hull ash (CALGreen Residential A4.403.2).
9.25	Nonresidential construction shall use cement and concrete made with recycled products (CALGreen Nonresidential A5.405).
9.26	Residential and nonresidential construction shall incorporate efficient framing techniques, where applicable (Residential: CALGreen A4.404, Nonresidential: A5.404.1).
9.27	Residential and nonresidential construction shall incorporate sustainably-sourced, regional, bio-based, and reused materials, where applicable and available (CALGreen Res. A4.405 and Nonres. A5.405; CAPCOA MISC-3).
9.28	Prior to construction, applicants shall prepare a construction waste management plan for individual construction projects, in accordance with local and state requirements (El Dorado County C&D Waste Ordinance; CALGreen mandatory measures 4.408, 5.408).

Policy #	Policy
9.29	A minimum of 65 percent of the non-hazardous construction waste generated at a construction site shall be recycled or salvaged for reuse (CALGreen A4.408.1; CAPCOA SW-2).
9.31	One hundred percent of trees, stumps, rocks, and associated vegetation and soils resulting primarily from land clearing associated with subdivision construction shall be reused or recycled, to the extent feasible (CALGreen Mandatory Measure 5.408.4).
9.32	Any covenants, conditions, and restrictions shall allow for on-site composting of residential yard waste and non-hazardous household food waste.
9.33	On-site reuse of compost and mulch shall be encouraged in privately-owned gardens and landscaping or within common landscaped areas in the Plan Area.
9.34	On-site composting of commercial food waste, landscaping green waste, and other forms of organic waste shall be encouraged in all Office Park, Commercial, and Public Facilities designations, in accordance with any applicable local and state regulations.
9.35	Easily-accessible, screened, and well-maintained recycling and composting areas shall be provided for the depositing, storage, and collection of all non-hazardous recyclable or compostable materials (including paper, plastic, glass, metal, and yard and food waste).

C.221 WATER CONSERVATION

9.36	Residential indoor water use shall be reduced by a minimum of 20 percent from the 2008 Plumbing Code baseline as demonstrated by the prescriptive fixture-based method or according to a water use baseline, or achieve the then-current Plumbing Code in effect at the time of construction , in accordance with CALGreen Mandatory Measures (CALGreen Residential 4.303 and Nonresidential 5.303; CAPCOA WUW-1).
9.37	Nonresidential indoor water use shall be encouraged to be reduced by a minimum of 30 percent as demonstrated by the prescriptive fixture-based method or according to a water use baseline, in accordance with CALGreen Nonresidential Voluntary Tier 1 Measures (CALGreen Nonresidential A5.303; CAPCOA WUW-1).
9.38	Maximum flow rates for residential kitchen sink faucets shall not be greater than 1.5 gallons per minute at 60 psi (CALGreen Residential A4.303.1; CAPCOA WUW-1).
9.39	Waterless urinals and toilets shall be encouraged in all Office Park, Commercial, and Public Facilities buildings, where applicable (CALGreen Residential A4.303.2; CAPCOA WUW-1).

Policy #	Policy
9.40	A backbone recycled water system shall be designed and installed throughout the Plan Area to supply recycled water to residential yards, commercial landscaping, park sites, landscape corridors, vineyards, and other landscaped spaces (CAPCOA WSW-1; EID Board Policy 7010).
9.41	Nonresidential buildings and facilities shall be dual-plumbed for potable and recycled water systems for toilet flushing when indoor recycled water is available for use, if allowed by the enforcing authority (CALGreen A5.305.5).
9.42	Outdoor water conservation measures shall include weather-based irrigation controllers, low-water consumption irrigation systems, the establishment of water budgets, and other measures where applicable (CALGreen Residential 4.304 and A4.304, Nonresidential 5.304; CAPCOA WUW-3,4).
9.43	Hydro-zoning techniques shall be incorporated into landscape designs for all post-construction landscapes (CALGreen A4.106.3; CAPCOA WUW-3).
9.44	A minimum 75 percent of the Plan Area planting palette shall feature California Central Valley and foothills native plant species as described in the most current edition of River-Friendly Landscape Guidelines and drought tolerant adaptive plant species (CALGreen A4.160.3; CAPCOA WUW-3, -5, -6). Neighborhood entry gateways and similar high visibility locations in the Plan Area may feature conventional ornamental or agricultural plant species.
9.45	Consistent with CALGreen Tier 2 voluntary measures, all non-public uses within the Plan Area shall limit the use of turf to no more than 25 percent of the total landscaped area (CALGreen A4.106.3; CAPCOA WUW-5).
9.46	The use of turf is not allowed on slopes greater than 25 percent where the toe of the slope is adjacent to an impermeable hardscape (Model Water Efficient Landscape Ordinance, Section 492.6).

OVERVIEW

The Village of Marble Valley, henceforth called Marble Valley is located south of Highway 50, about 3 miles east of El Dorado Hills and southwest of Cameron Park. Marble Valley is a 2,341 acre comprehensively planned community which will include a mixture of residential densities, commercial, agriculture, schools, parks and open spaces. At build-out, Marble Valley will accommodate as much as 3,236 dwelling units and 1,284 acres of natural open space. The open space element will comprise fifty-five percent of the projects total acreage. Higher density residential and commercial development will be located on the valley floor and lower density residential will be located on the surrounding wooded slopes. See Figure 1, Location Map.

Figure 1. Location Map of Marble Valley

Most of the development area is located within the Marble Creek watershed. The terrain is moderately steep with the creek flowing from Highway 50 southeast to its confluence with Deer Creek. Deer Creek drains south through Cameron Park and continues southerly for about two miles after crossing under Highway 50. It then turns and flows to the southwest, discharging into the Cosumnes River upstream of Highway 99.

Portions of the proposed development extend beyond the ridge lines of Marble Valley. To the east, relatively small areas drain to Deer Creek. To the west, relatively small areas drain to Strap Minor Creek and Pluckett Creek, both small watersheds that discharge into Deer Creek, just upstream of Latrobe Road.

The original conceptual design was to attenuate runoff to predevelopment conditions using several small dry basins to mitigate peak flows from specific areas of development. Another option was to utilize the large quarry that is located in the upstream portion of Marble Creek. After some preliminary modeling, key information supported a simpler approach.

Rather than constructing several small basins, all of the flood attenuation will be done at the most downstream road crossing over Marble Creek. The crossing is needed for development, and the temporary storage upstream of the road embankment is readily available. This crossing provides adequate attenuation for all of the Marble Valley development.

At this time, there is not enough design information to provide meaningful water quality facilities. It is expected that Site Design Water Quality Measures will provide additional attenuation and flow reduction through the developed areas of the project.

ANALYSIS

The purpose of this study was to analyze the drainage systems and determine facilities that will provide attenuation sufficient such that developed flows are equal to or less than existing conditions and there will be no increase in flood potential downstream of the project. It should also be noted that drainage facilities within the several development areas have not been evaluated because there is no site development information at this time.

Three scenarios were evaluated identified as A, B and C. Scenario A is Existing Conditions. Scenario B is based on the assumption that both Marble Valley and Lime Rock Valley are fully developed with attenuation at the road crossing described above. Scenario C is based on the assumption that Marble Valley is developed with no changes within Lime Rock Valley and the same road crossing as described above is used for attenuation.

Three design storms, the 2.33 year, the 10-year, and the 100-year, were used for the analysis. The 2.33 year storm was used because rainfall data were available. It is only slightly larger than the 2-year storm which typically would have been included if rainfall data were readily available.

SOFTWARE

Both the hydrologic and hydraulic analyses are based on procedures outlined in the County of El Dorado Drainage Manual, adopted 3-14-95. The modeling software that was used is from XP SWMM and does both hydrograph generation and hydraulic routing.

The XP-SWMM is a dynamic program, based on the EPA SWMM, with numerous improvements. The model will generate subshed runoff hydrographs and then route those hydrographs through the conveyance facilities, tracking and accounting for all of the runoff as it travels downstream for the duration of the storm. Time steps are typically between 3 to 30 seconds.

The XP-SWMM software is graphics based with numerous error routines and graphic aids to assist the modeler. The runoff model has numerous hydrologic methods available to generate runoff hydrographs. The hydraulics module transports the computed subshed runoff through any configuration of open and closed conduits, storage/treatment devices, pumps, and regulators. XP-SWMM is approved by FEMA for use to update or complete Flood Insurance Studies. Sacramento County uses XP-SWMM extensively.

HYDROLOGY

Main Stem of Deer Creek

There were two gages along Deer Creek where peak flow data were collected in the past and one gage identified as Deer Creek at Cameron Park where more recent peak flow data are available. The earlier two gages are Deer Creek near Shingle Springs and Deer Creek near Sloughhouse. The Sloughhouse gage is downstream of the confluence of Marble Valley Creek and Deer Creek while the other two are upstream of the confluence. Figures 2, 3, & 4 are plots of the respective peak flows at the three gages.

Figure 2. Peak Flows along Deer Cr near Shingle Springs, Gage #11335650, DA= 6.62 sq. mi.

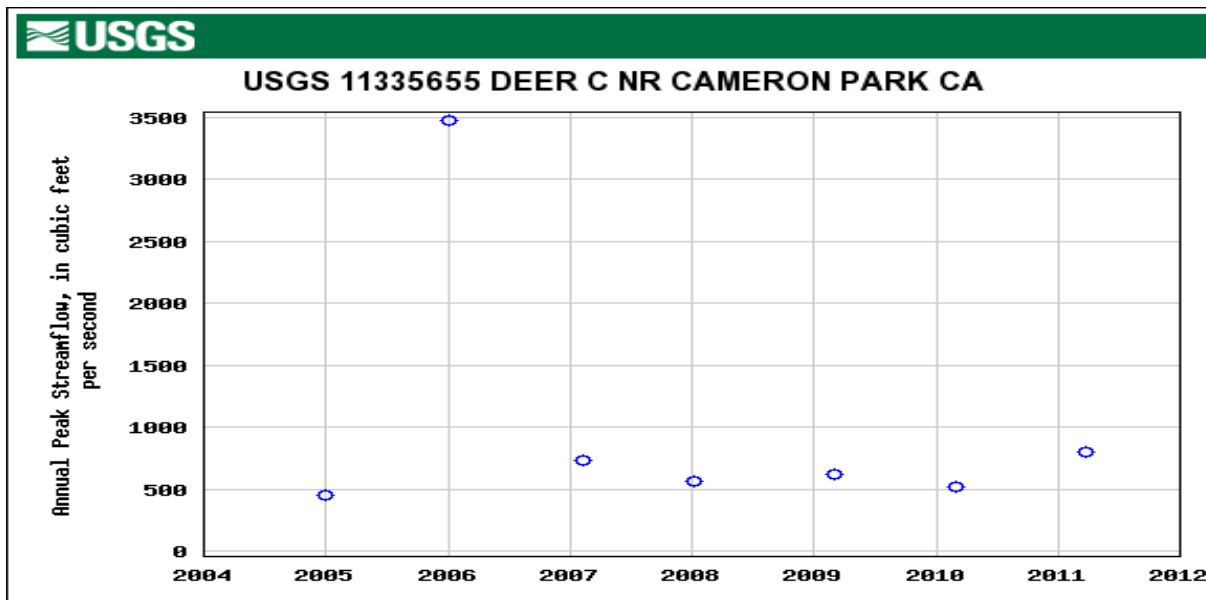

Figure 3. Peak Flows along Deer Creek near Cameron Park, Gage # 11335655, DA= 10.3 sq. mi

Figure 4. Peak Flows along Deer Creek near Sloughhouse, Gage # 11335700, DA=46.0 sq. mi.

Flood frequency data were also available at two of the gages. The statistical 100-year peak flow estimates, using Bulletin 17B (standardized flood-frequency analysis techniques) are 1,820 cfs at the Shingle Springs gage and 10,800 cfs at the Sloughhouse gage.

Subshed Analysis

The SCS Curve Number methodology was used within the XP-SWMM software to generate runoff hydrographs from the selected subsheds. Thirty-one subsheds were used to define the runoff

hydrographs from the Marble Valley development area. An additional thirteen sheds were modeled to define tributary areas of Deer Creek and Marble Creek upstream of the development.

Type D soils were assumed in all cases based on SCS soils information, the relatively steep slopes, and visual evidence of hard rock at or near the land surface. Soils are mostly within the Auburn series, silt loams, about 1 to 2 feet thick on bedrock. The hydrologic classification is Type D soils, low permeability. A curve number (CN) of 84 was used for all undeveloped areas based on interpretation of Table 2-2a from Soil Conservation Service-Technical Release 55.

There are several methods to compute time-of-concentration and/or catchment lag. Several methods were evaluated, and as expected, results varied because of the variety of slopes and shapes of the subsheds. Rather than select one of the methodologies, the modeler used the USGS Regional Flood-frequency Equations (Table A2.4.1, El Dorado County Drainage Manual) as a guide to determine a peak flow within the SCS hydrograph. Trial and error was used to select lag times that seemed reasonable and generated hydrographs with peak flows similar but generally larger compared to the peaks computed from the regression equation.

Locations of the shed boundaries are shown on Map 1, Shed Area Map. Table 1 provides a summary of basin parameters and 100-yr peak flows for existing and developed conditions.

In addition to the 100-year flows, the 2-yr and 10-yr flows were also determined and routed through the conveyance system. Appendix A provides a summary of the 2-,10-, and 100-year flows.

Please note that the regression equation shows a rapid decrease in unit runoff as shed size increases. The modeler was more comfortable with the larger flows. However, the results of the comparative analysis between existing and developed conditions should be similar.

HYDRAULICS

Most of the Marble Valley development drains to Marble Creek. Several small subsheds east of a ridge line drain to Deer Creek. There are also small Marble Valley subsheds that drain west into Strap Miner Creek or Plunkett Creek, which in turn, drain into Deer Creek.

A moderate increase in runoff is expected when Marble Valley develops. Normally, measures are taken to not increase downstream water levels to avoid impacts to downstream development. In this case, there is no development and there are no structures along Marble Valley Creek. Therefore, there would be no local impacts if the runoff increased and water levels were higher.

However, there is development along Deer Creek farther downstream. Therefore, the design of the drainage facilities will be to attenuate the Marble Valley development flows to equal or less than development flows measured downstream of the confluence of the Marble Creek development with Deer Creek which is just downstream of the confluence of Plunkett Creek with Deer Creek.

The goal of the attenuation is to mimic existing conditions or to reduce downstream flows if there are existing flooding issues downstream of the development. The analysis for the proposed attenuation focused on the 100-year storm because that is the size of storm that is most likely to impact downstream properties. The 2- and 10-year storms were also routed through the proposed facilities.

Results of the 2- and 10-year storm analyses indicate there is less attenuation compared to the 100-year analysis. This is mainly because the culvert sizing needs to be sufficiently large to safely pass the 100-year storm and the smaller storms pass more quickly. A smaller culvert would improve the attenuation during the smaller storms but would also generate greater upstream storage during the 100-year storm. This tradeoff was evaluated, but the culvert configuration was based solely on the design to safely pass the 100-year storm.

As stated earlier and currently not defined, Site Design Measures will be implemented as the development proceeds. These measures will reduce peak flows and volumes of smaller storms. The reductions will tend to mitigate the flow increases expected as a result of development. This is a secondary reason to focus the culvert design on the 100-year storm rather than any lesser storm.

These facilities would be part of the southern road crossing within the Marble Valley development at channel stationing 135+75. Preliminary facilities include a 7' wide by 5' high box culvert to attenuate the flows leaving Marble Valley and the flow along Deer Creek downstream of Plunkett Creek.

Please note that because of the timing of the peak flows along both Deer Creek and Marble Valley Creek, coupled with inflow from several side tributaries, significant attenuation is needed to attenuate the downstream peak of Deer Creek. The inflow upstream of the road embankment is approximately 1,450 cfs during the 100-year storm, and the outflow through the box culvert is about 800 cfs. Maximum upstream water depth is 30 feet, and the temporary storage is about 53 acre-feet. The storage area upstream of the road embankment fills and empties in about six hours. The major benefit of this approach is that detention facilities within Lime Rock Valley would not have to be constructed or maintained.

As a separate note, the depth and temporary storage at this proposed site would exceed Dam Safety requirements if applicable. Review of the regulations and a phone conversation with personnel at the Division of Dam Safety indicated that rail, roadway, and highway embankments are exempt from the regulation.

There is typically additional runoff from developed impervious surfaces. Table 2 provides a summary of the volumes of runoff for both existing and developed conditions. The developed conditions volume does not include any reductions gained from Design Site Measures that will be part of the development but are unknown at this time. Note that the runoff volumes are from the entire Deer Creek shed area. Subshed volumes are available if needed.

Table 2. Summary of Storm Volumes

Storm Event	Exist Cond Vol (af)	Dev. Cond Vol. (af)	Increase (af)
2-yr	1,544	1,570	26
10-yr	2,917	2,951	34
100-yr	4,848	4,889	41

It is expected that the development of Lime Rock Valley will occur concurrently or after Marble Valley develops. Because of the timing of flow peaks along Deer Creek in relation to the tributary peaks, it was determined that the attenuation along Marble Valley Creek would also be efficient to mitigate higher development flows from Lime Rock Valley. As such, two scenarios were compared to existing conditions. Scenario A is Existing Conditions. Scenario B is based on the assumption that both Marble Valley and Lime Rock Valley are fully developed. Scenario C is based on the assumption that Marble Valley is developed with no changes within Lime Rock Valley.

Please note that the culvert and embankment configuration at the road crossing was the same for both Scenarios B and C. As development proceeds, there may be a need or desire to “fine-tune” the culvert design. However, at this time in the development process, the proposed culvert would be adequate for either Scenario B or C.

Table 3 provides flow for existing and developed conditions at selected locations to show there will be no increase of flow along Deer Creek as a result of the Marble Valley development (Scenario B). **Map 1** provides flow information for both existing and developed conditions for the 100-year storm along the main stem of Marble Valley Creek and Deer Creek downstream of the confluence of Marble Valley Creek, also for Scenario B.

Table 3. Summary of 100-yr Flows at Select Locations for Scenario B

Description	Drainage Area (sq mi)	Model ID/ Chnl Stationing	Exist Flow (cfs)	Dev w/ Attenuation (cfs)
Deer Cr US of Marble Valley Cr Confluence	11.7	d180-185	5,490	5,530
Marble Valley Cr US of Confluence	2.74	175-179	1,700	860
Deer Cr DS of Confluence w/ MV Cr	14.4	d185-190	6,320	6,370
Deer Cr DS of confluence w/ Plunkett Cr-	26.8	DrCrDS	8,820	8,730

Table 4 provides similar information under Scenario C conditions. The peak flows are essentially the same at the critical analysis point downstream of the confluence with Plunkett Creek.

Table 4. Summary of 100-yr Flows at Select Locations for Scenario C

Description	Drainage Area (sq mi)	Model ID/ Chnl Stationing	Exist Flow (cfs)	Dev w/ Attenuation (cfs)
Deer Cr US of Confluence	11.7	d175-180	5,490	5,490
Marble Valley Cr US of Confluence	2.74	175-179	1,700	860
Deer Cr DS of Confluence w/ MV Cr	14.4	d185-190	6,320	6,390
Deer Cr DS of confluence w/ Plunkett Cr-	26.8	DrCrDS	8,820	8,680

Appendix B provides 2- and 10-year flow information at the same key locations. The attenuations are less compared to the 100-year flows. However, the water level increases are very small (0.1 feet or less) and are not considered significant because these water levels are lower compared to the 100-year water levels.

Note that the 100-year peak flow computed in this analysis, if projected downstream to Sloughhouse, would be larger compared to the flood frequency information presented earlier that was based on the Bulletin 17B procedures. Based on comparatively more intense rainfalls over the last 10-20 years, the higher peak flows from the XP SWMM modeling will be used.

The defined 100-year floodplain along Marble Valley Creek for developed conditions is shown on **Map 2** of this report. Appendix C provides additional modeling information. Electronic copies of the modeling files are available upon request.

WATER QUALITY

Water quality Best Management Practices (BMPs) will be implemented on a parcel by parcel basis to adhere to the most current NPDES Phase II Small MS4 General Permit and El Dorado County Storm Water Quality Standards, effective at the time of parcel entitlement. Lacking detailed parcel specific site plans, grading and utility design during the Specific Plan process, it is impossible to quantify, or identify locations of, specific Low Impact Design (LID) elements, Treatment Control Measures and Hydromodification Control Measures.

These measures are best implemented during the tentative map planning stage as more detailed, parcel specific, design information becomes available to assist in developing LID credits, to determine treatment control and hydromodification control extent or necessity.

Water quality Best Management Practices will be utilized to reduce urban runoff pollution to the maximum extent practicable.

DISCUSSION

As described earlier, the attenuation will be provided at the downstream road crossing. The downstream crossing will have a single box culvert, 5 feet high and 7.2 feet wide. Two additional design features are described. When the road crossings are in preliminary design, a second high-level culvert will be part of the embankment for each crossing, located at the 100-year water level at the upstream side of the embankment. This will act as an emergency spillway in an extreme event larger than the 100-year storm or if debris restricts high flow.

The second design feature is erosion control at the culvert outlets. The flow velocity in the culvert will be very high, and a rock rip rap erosion facility is recommended. The rock will probably include three layers, each layer having larger rock towards the surface. The erosion control configuration should be based on Corps of Engineers design criteria.

Timing of peak flows is very important for this project, and the model analysis is based on several simplifying assumptions. The rainfall intensity, distribution, and duration are all based on standard modeling procedures. Different storm shapes will generate different hydrograph shapes. In addition, the shape of the runoff hydrograph is also dependent on subshed characteristics and time of concentration.

The road crossings provide significant attenuation along Marble Creek and moderate attenuation along Deer Creek. If the time of concentration for the mainstem of Deer Creek is quicker than modeled, then the attenuation at the road crossings will be greater along Deer Creek than presented herein. If the estimated time-of-concentration for the mainstem is longer, the effect of the Marble Creek flows is less important, and the proposed development will not cause an increase in flood potential along the downstream reaches of Deer Creek.

1.0 INTRODUCTION

1.1 REPORT OVERVIEW

This study presents the results of a transportation impact analysis completed for the Village of Marble Valley Specific Plan (VMVSP) (project) in El Dorado Hills, California, which is an unincorporated area of El Dorado County (County). The project area is approximately 1,000 feet southeast of the US 50/Bass Lake Road interchange and is surrounded by the Cambridge Oaks residential development and US 50 to the north; Marble Ridge residential development and Valley View Specific Plan area to the west; Ryan Ranch residential development to the southwest; Sun Ridge Systems to the south; and Cameron Estates, the proposed Lime Rock Valley Specific Plan, Deer Creek Wastewater Treatment Plant, and Royal Equestrian Estates to the east.

The purpose of this impact analysis is to identify potential environmental impacts to transportation facilities as required by the California Environmental Quality Act (CEQA). This study was performed in accordance with the *El Dorado County Department of Transportation's Traffic Impact Study Protocols and Procedures*, and the scope of work developed in collaboration with County staff and Caltrans.

The remaining sections of this report document the proposed project, analysis methodologies, impacts and mitigations.

1.2 PROJECT DESCRIPTION

The proposed VMVSP includes the development of 3,236 dwelling units, 87 acres of public facility/recreational use, 475,000 square feet of commercial use, 35 acres for two public schools (k5/K8), 1,284 acres of open space, 55 acres of agricultural use, and 61 acres of new road impact areas and future right-of-way. Planned improvements are proposed for 1,875 acres of the 2,341-acre site. Most of the development would occur north of Deer Creek. The proposed project expands the Community Region of El Dorado Hills to include the VMVSP area. Figure 1, adapted from the project's *Notice of Preparation of a Draft Environmental Impact Report*, provides an overview of the proposed project and internal roadway network to support proposed land uses.

US 50 access will be through the US 50/Bass Lake Road and US 50/Cambridge Road interchanges. Marble Valley Parkway is proposed as a continuous roadway connecting the Bass Lake Road and Cambridge Road interchanges. A portion of Marble Valley Parkway is outside the plan area. Marble Lake Boulevard, which is planned as a four- to two-lane roadway, will provide the primary access roadway serving the project. Major intersections along Marble Lake Boulevard are planned to have roundabout control. Lime Rock Valley Boulevard will extend east of Marble Lake Boulevard as a two-lane roadway.

1.3 NOTICE OF PREPARATION COMMENTS REVIEW

The project's Notice of Preparation (NOP), which is required by CEQA was issued on February 20, 2013. The NOP and subsequent public scoping meeting provided interested parties the opportunity to formally comment on the project. This transportation analysis is informed by comments received during the NOP comment period. The following list summarizes transportation-related comments received by affected agencies and the general public.

Agency Comments Received

- Caltrans request to review the transportation scope. Caltrans recommended specific procedures for the analysis of state facilities. *Note: Coordination with Caltrans was completed during the NOP phase and included a meeting between Caltrans and El Dorado County to review study area and analysis methods.*
- CalFire request to review dead end road length calculations. *Note: The project has been reviewed and meets the requested length parameter.*

Public Comments Received (By Topic)

Public comments were incorporated into the environmental analysis as presented below.

General Traffic

- Impact of potential cut-through traffic on Cameron Estates roadways. *Note: No connections are proposed to Cameron Estates. Therefore, no evaluation of potential cut-through traffic on Cameron estates is necessary.*
- Concern regarding traffic congestion on Marble Valley Parkway. *Note: Analysis of Marble Valley Parkway is included in the study.*
- Need for a parallel and alternative route to US 50 on the south side of the freeway - *Note: Marble Valley Parkway will provide a parallel route to US 50 to the south.*

- Concern regarding congestion on US 50. *Note: Analysis of US 50 was coordinated with Caltrans and is included in the study.*
- Preclude future connections to the east, west and south as not to worsen cumulative impacts. *Note: The analysis does not assume new connections to the east, west, or south.*

Access

- Impact of proposed school siting and related congestion. *Note: The analysis includes the proposed schools.*
- Issue of increased traffic on rural County roads and related access. *Note: The analysis study area rural roadways where the project is anticipated to contribute traffic.*
- Provide additional freeway access. *Note: Analysis of US 50 was coordinated with Caltrans and is included in the study. Freeway access is proposed and is consistent with the County's CIP.*
- Need more than the proposed access point from the community in the event of an emergency evacuation. *Note: Emergency vehicle access locations are proposed with the project.*

Pedestrian, Bicycle, Transit

- Review pedestrian, bicycle, trails and vehicle circulation plans to determine good connectivity between land uses. *Note: Bicycle and pedestrian facilities are evaluated in the study.*
- Evaluate transit options for employees. *Note: transit facilities and services are evaluated in the study.*
- Provide pedestrian and bicycle access to transit especially at night. *Note: Bicycle and pedestrian facilities are evaluated in the study.*

Figure 1: Proposed Project **[Revised Figures Pending]**

DRAFT

2.0 REGULATORY SETTING

Existing transportation polices, laws, and regulations that would apply to the proposed project are summarized below. This information provides a context for the impact discussion related to the project's consistency with applicable regulatory conditions.

2.1 STATE

2.1.1 CALIFORNIA DEPARTMENT OF TRANSPORTATION

The California Department of Transportation (Caltrans) is responsible for operating and maintaining the State highway system. In the project vicinity, US 50 falls under Caltrans jurisdiction. Caltrans provides administrative support for transportation programming decisions made by the California Transportation Commission (CTC) for state funding programs. The State Transportation Improvement Program (STIP) is a multi-year capital improvement program that sets priorities and funds transportation projects envisioned in long-range transportation plans.

In June 2010, Caltrans approved a *Transportation Corridor Concept Report (TCCR) for Highway 50*. Caltrans prepares a TCCR, which is a long-range (20-year) planning document, for each state highway. The purpose of each TCCR is to identify existing route conditions and future needs and includes a concept LOS standard and the facility needs to maintain the concept LOS. The cover of the TCCR states that the *US 50 Corridor System Management Plan (Caltrans, May 2009)*, referred to as the CSMP, now serves as the TCCR from I-80 in West Sacramento to the Cedar Grove exit, which is east of the study area. Caltrans has established LOS F as the 'concept LOS' consistent with a four lane freeway with HOV lanes and auxiliary lanes. Since LOS F is identified as the concept LOS no further degradation of service from existing "F" is acceptable. The Concept LOS is a generalized LOS for large study segments used by Caltrans that reflect the minimum level of service or quality of operations acceptable for each route segment. However, the County General Plan LOS policy is used to identify impacts to US 50.

According to the *Guide for the Preparation of Traffic Impact Studies* (Caltrans, December 2002), the existing LOS should be maintained if a freeway facility is currently operating at an unacceptable LOS (e.g., LOS F). A project impact is said to occur if the project degrades LOS from an acceptable to unacceptable level. A project impact may also occur when the addition of project trips exacerbates existing LOS F conditions and leads to a perceptible increase in density on freeway mainline segments or ramp junctions, or a perceptible increase in service volumes in a weaving area. In addition, a project impact is said to occur

when the addition of project trips causes a queue on the off-ramp approach to a ramp terminal intersection to extend beyond its storage area and onto the freeway mainline.

2.2 LOCAL

2.2.1 SACRAMENTO AREA COUNCIL OF GOVERNMENTS

The Sacramento Area Council of Governments (SACOG) is an association of local governments in the six-county Sacramento Region. Its members include the counties of Sacramento, El Dorado, Placer, Sutter, Yolo, and Yuba as well as 22 cities. SACOG provides transportation planning and funding for the region, and serves as a forum for the study and resolution of regional issues. In addition to preparing the region's long-range transportation plan, SACOG assists in planning for transit, bicycle networks, clean air, and airport land uses.

The *Metropolitan Transportation Plan/Sustainable Communities Strategy (MTP/SCS) for 2035* (SACOG 2012) is a federally mandated long-range fiscally constrained transportation plan for the six-county area. Most of this area is designated a federal non-attainment area for ozone, indicating that the transportation system is required to meet stringent air quality emissions budgets to reduce pollutant levels that contribute to ozone formation. To receive federal funding, transportation projects nominated by cities, counties, and agencies must be consistent with the MTP/SCS.

The *2013/16 Metropolitan Transportation Improvement Program (MTIP)* is a list of transportation projects and programs to be funded and implemented over the next 3 years. SACOG submits this document to Caltrans and amends the program on a quarterly cycle. Only projects listed in the MTP/SCS may be included in the MTIP.

2.2.2 EL DORADO COUNTY TRANSPORTATION COMMISSION (EDCTC)

The EDCTC is the Regional Transportation Planning Agency (RTPA) for El Dorado County, except for that portion of the County within the Tahoe Basin, which is under the jurisdiction of the Tahoe Regional Planning Agency (TRPA).

One of the fundamental responsibilities which results from RTPA designation is the preparation of the County's Regional Transportation Plan. The *El Dorado County Regional Transportation Plan 2010 – 2030 (RTP)* is designed to be a blueprint for the systematic development of a balanced, comprehensive, multi-modal transportation system. The EDCTC submits the RTP to SACOG for inclusion in the MTP/SCS process.

The *El Dorado County Bicycle Transportation Plan - 2010 Update* provides a blueprint for the development of a bicycle transportation system on the western slope of El Dorado County. The plan updates the currently adopted El Dorado County Bicycle Master Plan, which was adopted in January 2005.

In May 2013, The EDCTC completed the *El Dorado Hills Community Transit Needs Assessment and US 50 Corridor Operations Plan* (Plan), which explores how the recent growth and projected development impact the need for transit services, and identifies the most appropriate type and level of service needed given the demand. The Plan represents a recommendation from the Western El Dorado County 2008 Short-Range Transit Plan to study and consider improved transit service in the El Dorado Hills area.

In August 2008, The EDCTC adopted the Coordinated Public Transit – Human Services Transportation Plan, which is intended to improve mobility of individuals who are disabled, elderly, or of low-income status. The plan focuses on identifying needs specific to those population groups and identifying strategies to meet their needs.

2.2.3 COUNTY OF EL DORADO

The County of El Dorado provides for the mobility of people and goods within El Dorado Hills, which is an unincorporated area of the County. All of the study intersections are within the County's jurisdiction.

The Transportation and Circulation Element of the El Dorado County General Plan (amended January 2009) outlines goals and policies that coordinate the transportation and circulation system with planned land uses. The following goals and their associated policies are relevant to the project.

- GOAL TC-1: To plan for and provide a unified, coordinated, and cost-efficient countywide road and highway system that ensures the safe, orderly, and efficient movement of people and goods.
- GOAL TC-X: To coordinate planning and implementation of roadway improvements with new development to maintain adequate levels of service on County roads. (The LOS policy specific to this project is described in Section 3.2.)
- GOAL TC-2: To promote a safe and efficient transit system that provides service to all residents, including senior citizens, youths, the disabled, and those without access to automobiles that also helps to reduce congestion, and improves the environment.
- GOAL TC-3: To reduce travel demand on the County's road system and maximize the operating efficiency of transportation facilities, thereby reducing the quantity of motor vehicle emissions and the amount of investment required in new or expanded facilities.
- GOAL TC-4: To provide a safe, continuous, and easily accessible non-motorized transportation system that facilitates the use of the viable alternative transportation modes.

- GOAL TC-5: To provide safe, continuous, and accessible sidewalks and pedestrian facilities as a viable alternative transportation mode.

The *El Dorado County Department of Transportation's Traffic Impact Study Protocols and Procedures* sets forth the procedures for conducting transportation analysis in the County. This traffic analysis is consistent with the County-established methods.

2.2.4 EL DORADO COUNTY TRANSIT AUTHORITY

El Dorado County Transit Authority (EDCTA) operates El Dorado Transit, which provides public transit service within the project area. El Dorado Hills is currently served by El Dorado Transit Dial-A-Ride services, Commuter Service, and the Iron Point Connector Route.

The El Dorado Park-and-Ride Facilities Master Plan, November 2007 calls for constructing nine new facilities over 20 years. The Plan calls for EDCTA to assume primary responsibility for existing Park-and-Ride facilities in the county and sets forth an annual program to fund the upkeep and operation. The Plan reiterates that demand exceeds supply at the Park-and-Ride lot, referred to as the El Dorado Hills Multi-modal Facility, located in the northeast corner of the White Rock Road/Latrobe Road intersection. In particular, Table 2 of the Plan suggests that future (year 2027) deficiency at this location is 172 additional spaces. The Plan identifies the construction of a 325-space multi-story parking garage with ground floor retail as priority project #12 in the Capital Improvement Program list. The proposed location is the existing Park-and-Ride lot.

The plan identifies the construction of the Bass Lake Hills Multi-modal Facility as the #1 priority. The concept is a condition of the Bass Lake Hills Specific Plan, which requires a designated site suitable for the construction of a 200-space Park-and-Ride facility. New development is also required to construct the first 100 spaces. The plan states that completion of the 200-space facility would fully address parking deficiencies in the Cameron Park area. Another facility, named the Marble Valley Park-and-Ride lot, has been proposed on the south side of US 50 at the Bass Lake Road interchange as part of the Marble Valley development previously approved by the County. However, the plan states that the Marble Valley Park-and-Ride lot is redundant with the Bass Lake Hills Multi-modal Facility and instead suggests that the developer provide an in-lieu payment towards another proposed Park-and-Ride facility such as the Bass Lake Hills Multi-modal Facility.

3.0 METHOD OF ANALYSIS

3.1 ANALYSIS PROCEDURES

Each study roadway facility was analyzed using the concept of Level of Service (LOS). LOS is a qualitative measure of traffic operating conditions whereby a letter grade, from A (the best) to F (the worst), is assigned. These grades represent the perspective of drivers and are an indication of the comfort and convenience associated with driving. In general, LOS A represents free-flow conditions with no congestion, and LOS F represents long delays and a facility that is operating at or near its functional capacity.

3.1.1 INTERSECTIONS

Traffic operations at the study intersections were analyzed using procedures and methodologies contained in the Highway Capacity Manual (HCM), Transportation Research Board, 2000 (as confirmed with County staff). These methodologies were applied using Synchro or SimTraffic software packages (Version 7), developed by Trafficware. Table 1 displays the delay range associated with each LOS category for signalized and unsignalized intersections based on the HCM.

The micro-simulation analysis software, SimTraffic, was used to analyze operations at the US 50/El Dorado Hills Boulevard interchange (Town Center Boulevard to Saratoga Way) to accurately analyze the effect of closely-spaced intersections. Simulation was requested by El Dorado County staff and Caltrans. The SimTraffic micro-simulation analysis applied the following methodology:

- The simulation was conducted for the entire peak hour (i.e., 60 minutes) using four 15-minute intervals with the peak hour factor applied in the second interval
- The results were based on the average of ten model runs
- Each of the ten simulation runs applied a ten-minute seeding time

The existing conditions SimTraffic model was validated to field measured traffic volumes and observed maximum vehicle queue lengths.

The HCM methodology determines the level of service (LOS) at signalized intersections by comparing the average control delay (i.e. delay resulting from initial deceleration, queue move-up time, time actually stopped, and final acceleration) per vehicle at the intersection to the established thresholds. The LOS for

traffic signal controlled and all-way stop controlled intersections is based on the average control delay for the entire intersection. For side-street stop-controlled intersections, the LOS is evaluated separately for each individual movement with delay reported for the critical (i.e., worst case) turning movement.

The following procedures and assumptions were applied for the analysis of existing and cumulative conditions:

- Roadway geometric data were gathered using aerial photographs and field observations.
- Peak hour traffic volumes were entered according to the peak hour of each intersection, except for the US 50/El Dorado Hills Boulevard interchange and adjacent intersections. For the interchange and adjacent intersections, a consistent peak hour was used so that volumes would balance (a requirement for accurate simulation analysis). The peak hour of the freeway is based traffic counts.
- Headway factors were adjusted based on the observed driver behavior. Drivers were observed to be more aggressive and use smaller headway to travel through the intersections near the US 50/El Dorado Hills Boulevard interchange.
- The peak hour factor (PHF) was calculated based on traffic counts and applied by approach, except for interchange areas, which applied the intersection PHF (a requirement for accurate simulation analysis), and under cumulative conditions where there was a significant increase in traffic volumes compared to existing conditions was forecast (Intersections 3-8, 13, and 14). A PHF of 0.95 was used at these locations.
- The counted pedestrian and bicycle volumes will be used with a minimum of two pedestrians per approach per peak hour.
- Heavy vehicle percentages were based on traffic counts and applied by movement.
- Signal phasing and timings were based on existing signal timing sheets provided by El Dorado County.
- Speeds for the model network were based on the posted speed limit.
- The PHF calculated for existing conditions was used for cumulative conditions, except for the Latrobe Road/Town Center Boulevard, US 50 EB Ramps/El Dorado Hills Boulevard, US 50WB Ramps/El Dorado Hills Boulevard, and the Saratoga Way/Park Drive/El Dorado Hills Boulevard intersections where a PHF of 0.95 was applied.

Source: Highway Capacity Manual (Transportation Research Board, 2010)

Level-of-Service	Average Control Delay (seconds/vehicle)		Description
	Signalized	Stop Controlled	
A	< 10.0	< 10.0	Very low delay. At signalized intersections, most vehicles do not stop.
B	10.1 to 20.0	10.1 to 15.0	Generally good progression of vehicles. Slight delays.
C	> 20.1 to 35.0	> 15.1 to 25.0	Fair progression. At signalized intersections, increased number of stopped vehicles.
D	> 35.1 to 55.0	> 25.1 to 35.0	Noticeable congestion. At signalized intersections, large portion of vehicles stopped.
E	> 55.1 to 80.0	> 35.1 to 50.0	Poor progression. High delays and frequent cycle failure.
F	> 80.0	> 50.0	Oversaturation. Forced flow. Extensive queuing.

TABLE 1: INTERSECTION LEVEL OF SERVICE CRITERIA

- The existing heavy vehicle percentages were maintained for cumulative conditions.
- The existing pedestrian and bicycle volumes were maintained for cumulative conditions.
- Traffic signals were optimized to serve future traffic volumes.

3.1.2 ROADWAY SEGMENTS

Roadway segment LOS was determined by comparing traffic volumes for selected roadway segments with peak hour LOS capacity thresholds. These thresholds are shown in Table 2 and were calculated based on the methodology contained in the Highway Capacity Manual (Transportation Research Board, 2000) and applied for the analysis of the 2004 El Dorado County General Plan.

TABLE 2: PEAK HOUR ROADWAY SEGMENT CAPACITIES BY FUNCTIONAL CLASSIFICATION AND LOS

Functional Classification	Lanes	Roadway Segment Capacity (Vehicles per Hour)				
		LOS A	LOS B	LOS C	LOS D	LOS E
Arterial (Divided)	4	N/A	N/A	1,850	3,220	3,290
	5	N/A	N/A	2,350	4,060	4,110
	6	N/A	N/A	2,760	4,680	4,710
	7	N/A	N/A	3,215	5,410	5,420
Arterial (Undivided)	2	N/A	N/A	850	1,540	1,650
	4	N/A	N/A	1,760	3,070	3,130

Notes: Peak hour roadway segment capacities based on the HCM 2010 and developed by the El Dorado County Community Development Agency, Long Range Planning. Five-lane capacity calculated by adding half of the difference between the two-lane and four-lane capacity to the four-lane capacity. Seven-lane capacity calculated by adding half of the difference between the four-lane and six-lane capacity to the four-lane capacity.

Source: Fehr & Peers, 2014

3.1.3 FREEWAY FACILITIES

The Highway Capacity Manual (Transportation Research Board, 2010), includes three different tiers of analysis for freeway facilities, which include planning, design, and operations analysis. The different tiers are intended to provide flexibility to the user in selecting the appropriate analysis level given available

resources (e.g., time and availability of analysis inputs) and the desired breadth of analysis coverage (e.g., more locations with less detail vs. fewer locations with more detail). For example, a planning level analysis requires relatively generalized analysis inputs and is regularly used when the breadth of coverage is more important than an analysis detail. For example, Caltrans uses planning level analysis for long-range planning efforts like the US 50 Corridor System Management Plan, which groups many freeway facilities into single analysis segments. The project level analysis in this report is based on operations analysis methods and analyzes each freeway facility separately, focusing on analysis detail instead of breadth of coverage. The operations analysis method is consistent with General Plan Policy TC-Xd and Caltrans traffic impact study guidelines.

Freeway operations were analyzed using the procedures and methodologies contained in the Highway Capacity Manual (Transportation Research Board, 2010). Table 3 describes the HCM LOS criteria for freeway mainline, freeway ramp junctions, and freeway weaving segments. For weaving segments, Caltrans District 3 prefers analysis based on the Leisch Method, which is described in the *Highway Design Manual* (Caltrans, last updated July 1, 2008). For consistency with both the El Dorado County General Plan and Caltrans preference, analysis of freeway weaving segments was conducted using both the HCM and Leisch Methods.

**TABLE 3:
FREEWAY FACILITY LEVEL OF SERVICE CRITERIA**

Level of Service	Density (vehicles/mile/lane)		
	Mainline	Ramp Junction	Weaving
A	≤ 11	≤ 10	≤ 10
B	11 – 18	10 – 20	10 – 20
C	18 – 26	20 – 28	20 – 28
D	26 – 35	28 – 35	28 – 35
E	35 – 45	> 35	> 35
F	> 45	Demand exceeds capacity	

Source: Transportation Research Board, 2010

3.2 THRESHOLDS OF SIGNIFICANCE

In accordance with CEQA, the effects of a project are evaluated to determine if they will result in a significant adverse impact on the environment. Informed by the 2012 California Environmental Quality Act (CEQA) Statutes and Guidelines, specifically Appendix G, the following criteria have been established to determine whether or not the project would have a significant impact on transportation and circulation.

The intent of CEQA Section 15064 is for the responsible agency to establish the thresholds in the context of what their specific values are towards environmental resources or impacts. Therefore, the standards of significance in this analysis are based on the framework presented in CEQA Appendix G and the current practice of the appropriate regulatory agencies. For most areas related to transportation and circulation, policies from the *2004 El Dorado County General Plan (amended January 2009)* and the *El Dorado County Department of Transportation's Traffic Impact Study Protocols and Procedures* were used. For the freeway system, Caltrans' standards were used. Implementation of the project would have a potentially significant impact on transportation and circulation if it causes any of the following outcomes:

- Conflict with an applicable plan, ordinance or policy establishing measures of effectiveness (MOEs) for the performance of the circulation system, taking into account all modes of transportation including mass transit and non-motorized travel and relevant components of the circulation system, including but not limited to intersections, streets, highways and freeways, pedestrian and bicycle paths, and mass transit. The following specific MOEs, which have been generated by the regulatory agencies, are applicable to this project.
 - General Plan Circulation Policy TC-Xd provides Level of Service standards for County-maintained roads and state highways as follows¹:
 - Level of Service (LOS) for County-maintained roads and state highways within the unincorporated areas of the county shall not be worse than LOS E in the Community Regions or LOS D in the Rural Centers and Rural Regions except as specified in Table TC-2. The volume to capacity ratio of the roadway segments listed in Table TC-2 as applicable shall not exceed the ratio specified in that table. *(Note: Two of the study roadways are presented in Table TC-2. Cambridge Road from Country Club Drive to Oxford Road is allowed a maximum volume-to-capacity (V/C) ratio of 1.07 until 2018. Cameron Park Drive from Robin Lane to Coach Lane is allowed a maximum V/C ratio of 1.11 until 2018.)*
 - If a project causes the peak hour level of service or volume/capacity ratio on a county road or state highway that would otherwise meet the County standards

¹ *El Dorado County Department of Transportation's Traffic Impact Study Protocols and Procedures, June 2008.*

(without the project) to exceed the LOS threshold, then the impact shall be considered significant.

- If any county road or state highway fails to meet the above listed county standards for peak hour level of service or volume/capacity ratios under existing conditions, and the project will “significantly worsen” conditions on the road or highway, then the impact shall be considered significant. The term “significantly worsen” is defined for the purpose of the paragraph according to General Plan Policy TC-Xe as follows:
 - A. A two (2) percent increase in traffic during the AM peak hour, PM peak hour or daily, OR
 - B. The addition of 100 or more daily trips, OR
 - C. The addition of 10 or more trips during the AM peak hour or the PM peak hour.
- Caltrans considers the following to be significant impacts:
 - Off-ramps with vehicle queues that extend into the ramp’s deceleration area or onto the freeway (i.e., exceed the available storage capacity);
 - Project traffic increases that cause any ramp’s merge/diverge level of service to be worse than the freeway’s level of service.
 - Any additional traffic generated by the project is added to a facility already operating at LOS F².
- Substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment).
- Result in inadequate emergency access.
- Conflict with adopted policies, plans, or programs regarding public transit, bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities.
 - The County has published the following issues and General Plan goals as relevant to traffic impact study assessments. The project may trigger a potentially significant impact if it’s in conflict with any of the following:
 - Access to Public Transit Services consistent with General Plan Circulation Element Goal TC-2: “To promote a safe and efficient transit system that provides service to all residents, including senior citizens, youths, the disabled, and those without

² The US 50 Transportation Corridor Concept Report identifies LOS F as the “Concept LOS” for US 50 from the Sacramento/El Dorado County line to Cameron Park Drive.

access to automobiles that also helps to reduce congestion, and improves the environment.”

- Transportation System Management consistent with General Plan Circulation Element Goal TC-3: “To reduce travel demand on the County’s road system and maximize the operating efficiency of transportation facilities, thereby reducing the quantity of motor vehicle emissions and the amount of investment required in new or expanded facilities.”
 - Non-Motorized Transportation consistent with General Plan Circulation Element Goal TC-4: “To provide a safe, continuous, and easily accessible non-motorized transportation system that facilitates the use of the viable alternative transportation modes.”
- Conflict with adopted policies, plans or programs regarding the delivery of goods and services.

DRAFT

4.0 EXISTING SETTING

4.1 STUDY AREA

Based on coordination with the El Dorado County Community Development Agency (Long Range Planning) staff and Caltrans, the expected distribution of project trips, and review of the *El Dorado County Department of Transportation's Traffic Impact Study Protocols and Procedures*, the following study intersections, roadway segments and freeway facilities have been selected for analysis during both the AM and PM peak hours. Figure 2 identifies the study area.

The following lists both existing intersections and intersections proposed as part of the project. Intersections 17 and 18 are applicable only to the Cumulative Conditions analysis. The applicable LOS target (LOS E for Community Regions and LOS D for Rural Regions) is identified for each study intersection.

Existing Intersections

1. Serrano Parkway/Bass Lake Road (LOS E)
2. Hollow Oak Drive/Bass Lake Road (LOS E)
3. Old Bass Lake Road/Bass Lake Road (LOS D)
4. Country Club Drive/Bass Lake Road (LOS D)
5. US 50 westbound ramps/Bass Lake Road (LOS D)
6. US 50 eastbound ramps/Bass Lake Road (LOS D)
7. Marble Mountain Road/Marble Valley Parkway (LOS D)
8. Marble Valley Parkway/Marble Ridge Road (LOS D)
9. Country Club Drive/Cambridge Road (LOS E)
10. Knollwood Drive/Cambridge Road (LOS E)
11. Merrychase Drive/Cambridge Road/ US 50 westbound ramps (LOS E)
12. US 50 eastbound ramps/Cambridge Road (LOS E)
13. Crazy Horse Road/Flying C Road/Cambridge Road (LOS E)
14. Flying C Road/Marble Valley Parkway (LOS E)
15. US 50 westbound ramps/El Dorado Hills Boulevard (LOS E)
16. US 50 eastbound ramps/Latrobe Road (LOS E)

Future Intersections:

17. Silva Valley Parkway/US 50 Westbound Ramps (Cumulative Conditions) (LOS E)
18. Silva Valley Parkway/US 50 Eastbound Ramps (Cumulative Conditions) (LOS E)
19. Saratoga Way/El Dorado Hills Boulevard
20. Park Drive/El Dorado Hills Boulevard
21. Town Center Boulevard/Latrobe Road
22. White Rock Road/Latrobe Road

Roadways:

- Bass Lake Road
- Cambridge Road
- Cameron Park Drive
- Country Club Drive
- Durock Road

Freeway Facilities:

- US 50 Mainline (Eastbound and Westbound) – Sacramento County to Cameron Park Drive
- El Dorado Hills Boulevard Interchange
- Bass Lake Road Interchange
- Cameron Park Interchange
- Silva Valley Parkway Interchange (Future Conditions)

4.2 ROADWAY NETWORK

The characteristics of the roadway system in the vicinity of the project are described below. Where applicable, the roadway designation given in the *2004 El Dorado County General Plan (amended January 2009)* is provided.

US Route 50 (US 50) is an east-west freeway located south of the project site. Generally, US 50 serves the majority of El Dorado County's major population centers and provides regional connections to the west (i.e., Sacramento) and to the east (i.e., State of Nevada). Primary access to the project from US 50 is provided via the US 50/Bass Lake Road and US 50/Cambridge Road interchanges. Near the project, westbound US 50 has a high-occupancy vehicle (HOV) lane and two general purpose travel lanes and eastbound US 50 has an HOV lane and three general purpose travel lanes west of Bass Lake Road and an HOV lane and two general purpose travel lanes between Bass Lake Road and Cambridge Road. The General Plan identifies US 50 as an eight lane freeway under future conditions. US 50 serves about 63,000 vehicles per day between Bass Lake Road and Cambridge Road.

The US 50/El Dorado Hills Boulevard/Latrobe Road interchange is currently under construction to improve the westbound on- and off-ramps, add 1,000 feet of auxiliary lane to westbound US 50, and provide westbound ramp metering and a dedicated HOV on-ramp lane. Future improvements are planned for this interchange as described in Section 6.1, Table 12.

Construction of the new US 50/Silva Valley Parkway/White Rock Road interchange is under construction. The interchange will be constructed in two phases. Phase 1 (CIP Project No: 71328) will construct a new connection to US 50 with new signalized slip on- and off-ramps westbound and a slip off-ramp and loop on-ramp eastbound. The mainline will have an overcrossing for Silva Valley Parkway and will be improved to include eastbound and westbound auxiliary lanes between the US 50/El Dorado Hills Boulevard/Latrobe Road interchange and the new US 50/Silva Valley interchange. Completion of Phase 1 is scheduled for 2016. Phase 2 will construct a westbound loop on-ramp and eastbound slip on-ramp (CIP Project No: 71345). The westbound loop on-ramp will begin the addition of an auxiliary lane that will continue westbound through the El Dorado Hills Boulevard interchange and terminate at the planned US 50/Empire Ranch interchange (CIP Project No: 53120).

The planned reconstruction of the US 50/Bass Lake Road interchange (CIP Project No: 71330 and GP148), will add a westbound auxiliary lane between the Bass Lake Road and Silva Valley Parkway interchanges.

Bass Lake Road is a two-lane roadway that generally follows at north-south alignment from north of US 50 to Green Valley Road. Marble Valley Parkway is the continuation of Bass Lake Road south of US 50 and

is proposed as the primary route to the project. The County's General Plan identifies Bass Lake Road as a four lane divided road near US 50 transitioning to a four lane undivided road and eventually a two-lane road as it continues north. Bass Lake Road serves about 10,000 vehicles per day north of US 50.

Cambridge Road is a two-lane roadway that generally follows a north-south alignment from north of US 50 to Green Valley Road. The project will access the US 50/ Cambridge Road interchange by way of Marble Valley Parkway with a connection to Flying C Road (north of the Cameron Estates entry gate). The County's General Plan identifies Cambridge Road as a major two lane road. Cambridge Road serves about 8,000 vehicles per day north of Country Club Drive.

Cameron Park Drive north of Palmer Drive, is a two-lane roadway to Green Valley Road. North of Green Valley Road, Cameron Park Drive continues as Starbuck Road. South of Palmer Drive, the roadway widens to four lanes with a center left-turn lane through the US 50 interchange to Coach Lane where it narrows again. Durock Road is the continuation of Cameron Park Drive south of Robin Lane. The County's General Plan identifies Cameron Park Drive as a four lane divided roadway from US 50 to Meder Road. Remaining portions are classified as a major two lane road. Cameron Park Drive serves about 20,000 vehicles per day south of Hacienda Drive.

Country Club Drive is a two-lane east-west roadway that generally runs parallel to and north of US 50. Country Club Drive provides connectivity between Bass Lake Road and Cameron Park Drive. It serves as a frontage road to US 50 and a connection between El Dorado Hills and Cameron Park communities. The County's General Plan identifies Country Club Drive as a major two lane road. Country Club Drive serves about 4,000 vehicles per day east of Bass Lake Road.

Flying "C" Road is two travel lanes south of the US 50 eastbound ramp-terminal intersection at the US 50/ Cambridge Road interchange. The project will access the US 50/ Cambridge Road interchange by way of Marble Valley Parkway with a connection to Flying C Road (north of the Cameron Estates entry gate). The County's General Plan does not specifically identify Flying "C" Road on the Circulation Map. Flying C Road serves about 500 vehicles per day.

El Dorado Hills Boulevard is a north-south roadway that continues as Salmon Falls Road on the north and Latrobe Road on the south. The roadway is four lanes with a center median between Park Drive and Governor Drive. Between US 50 and Park Drive, the roadway section widens to three lanes northbound to accommodate vehicle demand near the US 50 interchange. The County's General Plan identifies El Dorado Hills Boulevard as a four lane divided road except near US 50 where the designation changes to a six lane divided road. El Dorado Hills Boulevard serves about 22,000 vehicles per day north of Wilson Boulevard.

Latrobe Road is a north-south roadway and is the continuation of El Dorado Hills Boulevard south of US 50. Latrobe Road is six lanes near the US 50 interchange, narrows to four lanes south of White Rock Road and eventually narrows to two lanes as it continues south to connect with State Route 16 in Amador County. The General Plan identifies Latrobe Road as a six lane divided roadway near the US 50 interchange transitioning to a four lane divided road, then a two lane major road and eventually a two lane regional road serving the southwest portion of the County. Latrobe Road serves about 26,000 vehicles per day north of White Rock Road.

Marble Mountain Road is a relatively short two-lane roadway that serves rural residential properties south of US 50. The roadway is west of the project area but intersects Marble Valley Parkway near the US 50/Bass Lake Road interchange. The County's General Plan does not specifically identify Marble Mountain Road on the Circulation Map. Marble Mountain Road serves less than 200 vehicles per day.

Marble Valley Parkway is a two-lane roadway just south of US 50. The road terminates approximately 500 feet south of the US 50/Bass Lake Road interchange. Marble Valley Parkway is the continuation of Bass Lake Road south of US 50 and is the primary route to the proposed project. The County's General Plan does not specifically identify Marble Valley Parkway on the Circulation Map. Marble Valley Parkway serves less than 200 vehicles per day.

Serrano Parkway primarily serves residential land uses west of Bass Lake Road. The roadway provides one lane in each direction with a landscaped median west of Bass Lake Road. A new traffic signal is being installed at the Bass Lake Road/Silva Valley Parkway intersection as part of improvement to add the east leg to the intersection. The General Plan identifies this segment of Serrano Parkway as a major two lane road. Serrano Parkway serves about 5,000 vehicles per day west of Bass Lake Road.

Silva Valley Parkway is a north-south roadway that generally runs parallel to El Dorado Hills Boulevard north of US 50. Silva Valley Parkway ranges from two lanes to four lanes with a center median within the study area. The General Plan identifies Silva Valley Parkway as a four lane divided road. A new US 50 interchange at Silva Valley/White Rock Road is planned and included in the Cumulative conditions transportation analysis. The interchange project provides a realigned Silva Valley Parkway that will connect to the existing four-lane Silva Valley Parkway to the north and the existing two lane White Rock Road on the south. A new signalized intersection will be installed where the new Silva Valley Parkway will intersect old White Rock Road on the south.

White Rock Road is the continuation of Silva Valley Parkway south of US 50. White Rock Road is predominately a two or three lane roadway until west of Latrobe Road where the cross section widens to four lanes. White Rock Road was recently widened east of Latrobe Road to Monte Verde Drive to accommodate four lanes, sidewalks and Class II bicycle lanes. The General Plan identifies White Rock Road

as a six lane divided road east of Latrobe Road and a four lane divided road west of Latrobe Road. The US 50/Silva Valley Parkway/White Rock Road interchange will modify the roadway alignment and introduce a new signalized intersection at the intersection of White Rock Road/Existing Silva Valley Parkway/New Silva Valley Parkway and is assumed under Cumulative conditions. White Rock Road serves about 9,000 vehicles per day south of US 50.

4.3 EXISTING CONDITIONS PEAK HOUR TRAFFIC VOLUMES

Intersection, roadway segment, and freeway counts were collected to determine the existing traffic operations of study facilities. Weather conditions were generally dry and local schools were in full session, during the traffic count data collection.

For study intersections, AM peak period (7 AM to 9 AM) and PM peak period (4 PM to 6 PM) intersection turning movement counts were collected in May 2012 and January 2013. For study roadways, 24-hour traffic counts were collected in May 2012. Construction was ongoing at the US 50/El Dorado Hills Boulevard interchange. Field observations conducted during the AM and PM peak periods identified extensive vehicle queuing near the US 50/El Dorado Hills Boulevard interchange, with the longest queues southbound during the AM peak hour and northbound during the PM peak hour. However, all queued vehicles were served during the peak hour, so the traffic counts are representative of peak hour travel demand. As discussed in Section 3.1.1, the Latrobe Road/Town Center Boulevard, US 50 EB Ramps/El Dorado Hills Boulevard, US 50WB Ramps/El Dorado Hills Boulevard, and the Saratoga Way/Park Drive/El Dorado Hills Boulevard intersections were analyzed using SimTraffic micro-simulation with a common analysis hour (a requirement for accurate simulation analysis).

Each of the other study intersection's peak hours within the peak period was used for the analysis. For the majority of study intersections, the counts indicate that the AM peak hour is between 7:15 AM and 8:15 AM and the PM peak hour is between 5:00 PM and 6:00 PM. Figure 3 provides peak hour traffic volumes, lane configurations and traffic controls at each of the study intersections. Following is a list of both existing intersections and intersections proposed as part of the project.

Roadway segment traffic counts were collected for 20 roadway segments on Bass Lake Road, Cambridge Road, Cameron Park Drive, Country Club Drive, and Durock Road.

For US 50, directional traffic counts were collected during the AM peak period (6 AM to 9 AM) and PM peak period (3 PM to 6 PM) and included vehicle classification (i.e., automobiles and trucks) and vehicles using the high occupancy vehicle (HOV) lanes. The freeway traffic counts were conducted midweek (i.e., Tuesday, Wednesday, and Thursday) in August 2013. The August 2013 traffic counts were verified for

reasonableness by comparing to traffic data from Caltrans' Performance Measurement System (PeMS) and the Transportation Systems Network (TSN) data. PeMS data is collected continuously from traffic counts detectors located in the travel lanes of freeway facilities (HOV, general purpose, and on- and off-ramps). The TSN data includes an estimate of peak hour traffic based on seven day traffic counts. Figure 4 provides peak hour traffic volumes and lane configurations on US 50. Based on the August 2013 counts, heavy vehicles (i.e., trucks) represented one- and two-percent of westbound traffic during the morning and evening peak hours, respectively. In the eastbound direction, heavy vehicles represented four- and one-percent of traffic during the morning and evening peak hours, respectively. These peak hour heavy vehicle percentages are lower than rates based on daily traffic volumes, since heavy vehicles avoid peak hour conditions.

4.4 EXISTING CONDITIONS PEAK HOUR VEHICLE LEVEL OF SERVICE

4.4.1 INTERSECTIONS

Table 4 summarizes existing conditions AM and PM peak hour Level of Service (LOS) for the study intersections. The LOS of a facility is a qualitative measure used to describe operating conditions. LOS ranges from A (best), which represents short delays, to LOS F (worst), which represents long delays and a facility that is operating at or near its functional capacity.

As described in Section 2.2, an intersection that is operating at LOS D or better in a Rural Region or LOS E or better in a Community Region is considered to operate at an acceptable level. The following three study intersections operate at LOS F:

- Bass Lake Road/Country Club Drive – LOS F during the AM peak hour
- Bass Lake Road/US 50 eastbound ramps – LOS F during the PM peak hour
- Cambridge Drive/Knollwood Drive – LOS F during the AM peak hour

All three intersections have side-street stop control.

Detailed LOS analysis sheets are contained in Appendix A. See section 3.1 and Table 1 for a definition of LOS as it relates to intersection delay.

TABLE 4: PEAK HOUR LEVEL OF SERVICE – EXISTING CONDITIONS (INTERSECTION)

TABLE 5: PEAK HOUR LEVEL OF SERVICE - EXISTING CONDITIONS (ROADWAY SEGMENTS)

Table 5 summarizes existing conditions AM and PM peak hour LOS for the study roadways. All study area roadway segments operate acceptably, with most operating at LOS C or better. Detailed LOS analysis sheets are contained in Appendix A. See section 3.1 and Table 2 for a definition of LOS as it relates to roadway segments.

4.4.2 ROADWAY SEGMENTS

Notes: SSSC = side-street stop-control, AWSC = all-way stop control
bold text indicates LOS worse than established threshold. *italic and underlined* text identifies a potential impact.
 The average delay is measured in seconds per vehicle. For signalized and AWSC intersections, the delay shown is the average control delay for the overall intersection. For SSSC intersections, the LOS and control delay for the worst movement is shown.
 Intersection LOS and delay is calculated based on the procedures and methodology contained in the HCM (TRB, 2000). Intersections 1-14 and 22 are analyzed in Synchro 7. Intersections 15-16 and 19-21 are analyzed in SimTraffic. Source: Fehr & Peers, 2014

4.4.3 FREEWAY FACILITIES

Freeway facilities in the County are under the jurisdiction of the California Department of Transportation (Caltrans). In recent years, US 50 and interchanges within or proximate to the study area have undergone or are undergoing various improvements to enhance traffic operations. These improvements include: High Occupancy Vehicle (HOV) lanes east to Cameron Park Drive and modifications to the US 50/El Dorado Hills Boulevard Latrobe Road interchange westbound ramps (currently under construction). As described in Section 4.2, the US 50/Silva Parkway/Latrobe Road interchange will be constructed within the next few years.

Table 6 summarizes existing peak hour freeway operating conditions. All of the study facilities currently operate acceptably. Detailed LOS analysis sheets are contained in Appendix A. See section 3.1 and Table 3 for a definition of LOS as it relates to freeway facilities.

4.5 PEDESTRIAN CIRCULATION

Attached or landscape-separated detached sidewalks are provided intermittently throughout the project study area. Given the primarily rural residential nature of El Dorado Hills and Cameron Park, it is not necessarily the desire to provide sidewalks in all areas. That said, some of the following major roadway facilities lack sidewalks and result in pedestrian network gaps:

- Both sides of Bass Lake Road from US 50 to Hollow Oak Drive; however, this area currently serves only a few large residential parcels with no services within walking distance.
- Both sides of Country Club Drive west of Trinidad Drive; however, there are limited land uses that would benefit from sidewalks near the street.
- Sidewalk is also missing on the south side of Country Club Drive between Merry Chase Drive and opposite Placitas Drive (Cameron Park Library driveway). This segment is adjacent to Blue Oak Elementary/Charter Montessori School and Camerado Springs Middle School.
- Country Club Drive lacks sidewalk from approximately 300 feet east of Placitas Drive to 200 west of Cameron Park Drive.
- Cambridge Road and Flying "C" Road (south of US 50) lack sidewalk except for the east side near the US 50 interchange.

Most study intersections are unsignalized without physical pedestrian features such as curb ramps and marked crosswalks. The three signalized study intersections do provide controlled pedestrian crossings or are otherwise restricted. As described in Section 4.6 below, Class I bicycle paths double as pedestrian facilities. For example, the Class I path along the east side of Bass Lake Road between Hollow Oak Drive and Serrano Parkway provide redundant pedestrian facilities to the detached sidewalk on the west side.

4.6 BICYCLE CIRCULATION

Existing and proposed bicycle facilities within the study area are displayed in Figure 5. Bicycle facilities can be classified into three categories.

- Class I Bicycle Path– Off-street bike paths within exclusive right-of-way; usually shared with pedestrians
- Class II Bicycle Lane – Striped on-road bike lanes adjacent to the outside travel lane on preferred corridors for biking
- Class III Bicycle Route– Shared on-road facility, usually delineated by signage and pavement markings

According to the *El Dorado Bicycle Transportation Plan, 2010 Update (El Dorado County Transportation Commission)*, mapping information provided by the County, and field observations, the following major bikeway facilities are present within the study area:

- Class II bicycle lanes on Serrano Parkway , White Rock Road, Latrobe Road and portions of Silva Valley Parkway, Country Club and El Dorado Hills Drive
- Class I bicycle path, Bass Lake Road (Hollow Oak Drive to Serrano Parkway), New York Creek Nature Trail, which is adjacent to El Dorado Hills Drive on the east side between Serrano Parkway to St Andrews Drive

Figure 5 identifies existing and planned bikeways presented in the *El Dorado Bicycle Transportation Plan, 2010 Update and the Sacramento Area Council of Governments (SACOG) Metropolitan Transportation Plan/Sustainable Communities Strategy (MTP/SCS) for 2035*.

DRAFT

4.7 TRANSIT

El Dorado County Transit Authority (El Dorado Transit) provides public transit service within the project area. El Dorado Hills is currently served by El Dorado Transit Dial-A-Ride services, Commuter Service, and the Iron Point Connector Route. Both the Commuter Service and the Iron Point Connector Route serve only the El Dorado Hills Park-and-Ride Lot and do not circulate within the community.

In May 2013, The EDCTC completed the *El Dorado Hills Community Transit Needs Assessment and US 50 Corridor Operations Plan* (Plan), which explores how the recent growth and projected development impact the need for transit services, and identifies the most appropriate type and level of service needed given the demand. All three services are addressed in the Plan and are described briefly below.

- **Dial-A-Ride** service is a demand response service designed for seniors and disabled passengers, with limited access available for the general public. The service is available on a first-come, first-serve basis Monday through Friday between the hours of 7:30 AM and 5:00 PM, and between 8:00 AM and 5:00 PM on Saturdays and Sundays. El Dorado Hills is one of twelve geographic zone service areas.
- **Commuter Service** is offered Monday through Friday between El Dorado County and downtown Sacramento. Morning departures from El Dorado County locations are scheduled from 5:10 AM to 8:00 AM, and afternoon eastbound departures from Sacramento occur from 2:40 PM to 6:00 PM. A reverse commuting service is offered. The El Dorado Hills Park-and-Ride located in Town Center at the White Rock Road/Post Street intersection is the nearest stop location for the project. According to the Plan, nearly half of commute passengers boarded at the El Dorado Hills Park-and-Ride in the mornings, which makes this location the highest boarding stop offered as part of the Commuter Service.
- **Iron Point Connector (IPC) Route** provides direct service from El Dorado County to Folsom with connections to Sacramento Regional Transit light rail on weekdays. This route runs twice in the morning and twice in the afternoon from the Central Transit Center to the Iron Point Light Rail Station in Folsom. The El Dorado Hills Park-and-Ride located in Town Center at the White Rock Road/Post Street intersection is the nearest stop location for the project.
- **Cameron Park Route** is a fixed-route service, which begins at the Missouri Flat Transfer Center in Placerville, serves the Folsom Lake College/El Dorado Center, then continues to Cameron Park. After serving Cameron Park in a clockwise direction, the route serves the Cambridge Park-and-Ride and returns via Country Club Drive. The Cameron Park Route operates four runs daily and

one morning express run with limited stops. Deviations are not permitted on the express run. Monthly ridership was 3,000 passengers for fiscal year 2011-2012.³

The El Dorado Hills Park-and-Ride lot provides 120 parking spaces. The Plan reports that parking demand exceeds supply. Specifically, Table 19 of the Plan reports 108-percent parking utilization in 2005 for the El Dorado Park-and-Ride based on Sacramento Area Council of Governments and Caltrans data. Similarly, the Cambridge Road Park-and-Ride lot was reported to have 142-percent parking utilization in 2005; however, this lot was expanded in size in 2006.

The Plan also describes other transit providers that serve western El Dorado County, including the Senior Shuttle Program which has recently initiated service in El Dorado Hills.

³ Ridership data derived from El Dorado Transit Administrative Operations Reports, July-December 2010; Summary report January-June, 2011 presented in the El Dorado Hills Community Transit Needs Assessment and US 50 Corridor Operations Plan, May 2013.

5.0 EXISTING PLUS PROJECT CONDITIONS

5.1 TRIP GENERATION

Based on information contained in the Notice of Preparation and subsequent correspondence with County staff and the applicant, Fehr & Peers prepared trip generation estimates for the project based on methodologies and trip rates presented in Trip Generation, 9th Edition (Institute of Transportation Engineers), with adjustments to account for internal vehicle trips and walking trips given the mix of land use proposed and the location of the project relative to other services.

This traffic study determined that the combined effects of the Project's land use, location, and development scale would contribute to a reduction in off-site average weekday vehicle "trips" (e.g., one vehicle trip is when a person drives from their home to shopping or their job. Their return drive home is another trip). This reduction is due largely to the Project's proximity to commercial and retail services and connections between the project and these services. That is, most of the reduction in total off-site vehicle trips generated by the Project is attributable to those trips beginning on the Project site, traveling to adjacent services, and ending on the Project site without using off-site roadways or by walking.

Traditionally, traffic engineers and transportation planners have estimated internalization of project trips using one of two methods. First, they would estimate it based on their professional judgment. Alternatively, professionals relied on the Institute of Transportation Engineers' (ITE) internalization methodology presented in the ITE Trip Generation Handbook. Although this has been applied in thousands of studies in California, the methodology was limited as it was based on only six surveys in Florida. Additionally, the ITE internalization methodology only accounts for the land use types on the mixed-use site. Given the limited input information (land use amount and type) and the limited range of data (six surveys), the accuracy of the internalization estimates has recently been found to generally under-estimate internalization of trips from mixed-use projects.

Recognizing the limitations of the simplified methodology applied in the ITE handbook, the United States Environmental Protection Agency commissioned a study to develop a more substantial, statistically superior methodology. This methodology, identified as MXD (or mixed-use development trip generation), begins with ITE rates and developed trip internalization estimates based on a series of factors tied to numerous site attributes. It should also be noted that the MXD model has been developed in cooperation with the US Environmental Protection Agency (EPA) and ITE and that ITE is currently reviewing the model for potential inclusion in their updated recommended practice for evaluating MXD projects. The MXD methodology is described in greater detail below.

MXD Trip Internalization Methodology

The internal capture percentage reported is not an "assumed" number, but rather is a number that was derived using a best practices trip generation model designed specifically for mixed-use development (MXD) projects and estimates trip generation and internal capture by adjusting trip generation rates to account for the influence of built environment variables. A variety of research studies have demonstrated that these variables influence vehicle trip generation.

The MXD model used was developed based on household travel survey data obtained from 239 existing mixed-use developments in six metropolitan regions throughout the U.S., including developments in Sacramento. The internal capture percentage calculated for the project is reflective of the land uses that would be developed as part of the Project and land use near the project, which would reduce the need to travel beyond the Project site or surrounding area. A set of 16 independent mixed use sites that were not included in the initial model were tested to help validate the model. Among the validation sites, use of the MXD model produced superior statistical performance when comparing the model results to observed data. Given the statistical robustness of the MXD model, it was deemed the most appropriate approach for estimating internalization of project trips.

MXD Model Inputs and Trip Generation Estimates

To determine the amount of trips that would be internal to the Project site, an MXD trip generation estimate was prepared. The MXD analysis first begins with gross trip rates identified in the Institute of Transportation Engineers' Trip Generation (9th Edition, 2012). It then incorporates the MXD methodology for "matching" trips to estimate the amount of internalization within the project site. Table 7 summarizes project land use, assumed trip rates, calculated trip generation totals, and MXD adjustments.

The entire project is projected to generate about 31,020 daily vehicle trips, 2,380 AM peak hour vehicle trips and 3,360 PM peak hour vehicle trips. The daily total includes a reduction of about 8,700 vehicle trips for internalization, which are vehicle trips made that remain within the project site, which includes internalization school trips and local-serving retail trips. Please note that school trip internalization was capped at 75% (75% of all school trips will stay internal to the site) and internalization of local-serving retail trips was capped at 60%. The reduction in schools trips is most notable in the AM peak hour. An additional reduction of 14 vehicle trips was made in acknowledgement of feasible walking trips in lieu of vehicle trips.

5.2 TRIP DISTRIBUTION AND ASSIGNMENT

The expected distribution of project trips is shown on Figure 6. The distribution was developed using the following sources and analytical techniques:

- Existing travel patterns based on the existing traffic counts
- Traffic assignment using the validated base year El Dorado County travel demand forecasting model
- Project access and internal circulation

As shown on Figure 6, the largest share of project trips (61 percent) will use US 50 to/from the west in the morning and evening with 23 percent traveling on US 50 to/from the east. Travel to/from the north on Bass Lake Road is 7 percent. Figure 7 shows only project trips based on the trip distribution shown on Figure 6. The resulting AM and PM peak hour traffic volumes under existing plus project conditions are presented on Figure 8.

5.3 PEAK HOUR VEHICLE LEVEL OF SERVICE

5.3.1 INTERSECTIONS

Analysis results, which are presented in Table 8, indicate that many of the study intersections that are stop controlled will operate unacceptably with increased traffic from build-out of the proposed project added to existing conditions. Traffic generated by the project result in potential impacts at the following locations:

- Bass Lake Road/Serrano Parkway (Intersection 1) – This intersection operates acceptably at LOS D and B during the AM and PM peak hours, respectively, without the project. The project results in unacceptable (LOS F) conditions during the AM peak hour.
- Bass Lake Road/Country Club Drive (Intersection 4) – This intersection is located in the County's Rural Region and is subject to the LOS D significance threshold. This intersection operates unacceptably at LOS F without the project during the AM peak hour and acceptably at LOS C during the PM peak hour. According to established significance criteria, the project is projected to "significantly worsen" conditions, since it would add more than 10 trips to the intersection during the AM peak hour operations. The project would also result in unacceptable (LOS F) conditions during the PM peak hour.
- Bass Lake Road/US 50 westbound ramps (Intersection 5) – This intersection is located in the County's Rural Region and is subject to the LOS D significance threshold. This intersection operates acceptably at LOS B and LOS C during the AM and PM peak hours, respectively, without the project. The project results in unacceptable (LOS F) conditions during the AM and PM peak hours.
- Bass Lake Road/US 50 eastbound ramps (Intersection 6) – This intersection is located in the County's Rural Region and is subject to the LOS D significance threshold. This intersection operates acceptably at LOS C during the AM peak hour and unacceptably at LOS F during the PM peak hour without the project. The project would also result in unacceptable (LOS F) conditions during the AM peak hour, and according to established significance criteria, the project is projected to "significantly worsen" conditions, since it would add more than 10 trips to the intersection during the PM peak hour.
- Marble Valley Parkway/Marble Mountain Road (Intersection 7) – This intersection is located in the County's Rural Region and is subject to the LOS D significance threshold. This intersection operates acceptably at LOS A without the project during the AM and PM peak hours. The project results in unacceptable (LOS F) conditions during the AM and PM peak hours.
- Marble Valley Parkway/Marble Ridge Road (Intersection 8) – This intersection is located in the County's Rural Region and is subject to the LOS D significance threshold. This intersection

operates acceptably at LOS A without the project during the AM and PM peak hours. The project results in unacceptable (LOS F) conditions during the AM and PM peak hours.

- Cambridge Road/Country Club Drive (Intersection 9) – This intersection operates acceptably at LOS E and C during the AM and PM peak hours, respectively, without the project. The project results in unacceptable (LOS F) conditions during the AM peak hour.
- Cambridge Road/Knollwood Drive (Intersection 10) – This intersection operates unacceptably at LOS F during the AM peak hour and acceptably at LOS E during the PM peak hour without the project. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM peak hour. The project would also result in unacceptable (LOS F) conditions during the PM peak hour.
- Cambridge Road/US 50 eastbound ramps (Intersection 12) – This intersection operates acceptably at LOS B and E during the AM and PM peak hours, respectively, without the project. The project results in unacceptable (LOS F) conditions during the AM and PM peak hours.
- Cambridge Road/Flying C Road/Crazy Horse Road (Intersection 13) – This intersection operates acceptably at LOS B during the AM and PM peak hours without the project. The project results in unacceptable (LOS F) conditions during the AM peak hour.
- El Dorado Hills Boulevard/Park Drive/Saratoga Way (Intersection 19) – This intersection operates acceptably at LOS D and C during the AM and PM peak hours, respectively, without the project. The project results in unacceptable (LOS F) conditions during the AM peak hour.
- Latrobe Road/Town Center Drive (Intersection 21) – This intersection operates acceptably at LOS C and E during the AM and PM peak hours, respectively, without the project. The project results in unacceptable (LOS F) conditions during the PM peak hour.

5.3.2 ROADWAY SEGMENTS

Analysis results, which are presented in Table 9, indicate that all study roadway segments will operate acceptably. Traffic generated by the project is not anticipated to result in roadway segment impacts according to established significance criteria. A comparison of the results in Table 9 to the results in Table 8 shows that the number of through travel lanes on the study area roadways is adequate, but that improvements are needed at intersections, which are the locations where drivers experience delay traveling through the study area.

Intersection	LOS Target	Control	Existing Conditions (LOS / Delay)		Existing Plus Project (LOS / Delay)

21. Latrobe Road/Town Center Drive	E	Signal	C / 29	E / 75	C / 28	<u>F / 165</u>
22. Latrobe Road/White Road	E	Signal	C / 35	D / 44	D / 35	D / 44

Notes: SSSC = side-street stop-control, AWSC = all-way stop control

Bold text indicates LOS worse than established threshold. *Italic and underlined* text identifies a potential impact.

The average delay is measured in seconds per vehicle. For signalized and AWSC intersections, the delay shown is the average control delay for the overall intersection. For SSSC intersections, the LOS and control delay for the worst movement is shown.

Intersection LOS and delay is calculated based on the procedures and methodology contained in the HCM (TRB, 2000). Intersections 1-14 and 22 are analyzed in Synchro 7. Intersections 15-16 and 19-21 are analyzed in SimTraffic.

Source: Fehr & Peers, 2014

5.3.3 FREEWAY FACILITIES

Analysis results, which are presented in Table 10, indicate that all but three study freeway facilities will operate acceptably. Traffic generated by the project will result in LOS F conditions at the US 50 westbound on-ramp from Bass Lake Road, the westbound off-ramp to El Dorado Hills Boulevard, and the westbound on-ramp from El Dorado Hills Boulevard.

DRAFT

5.4 PEDESTRIAN CIRCULATION

The project proposes pedestrian facilities by implementing a comprehensive network of pedestrian trails and pathways to provide connectivity among land uses for non-motorized transportation and public recreational enjoyment throughout the 4-mile long valley. The proposed trails are designed as paved Class I multi-use paths along the three primary roadways of Marble Valley Parkway, Marble Lake Boulevard (nicknamed "The Gateway Mile") and Lime Rock Valley Road to serve the proposed residential, commercial, and public facilities in the northern half of the community. Less formal trails are proposed to traverse the preserved open space areas. Pathways will lead to the proposed Foundation Regional Park in the southern portion of the community and a Class I bike path will connect through the proposed Lime Rock Valley Specific Plan to the El Dorado Trail.

5.5 BICYCLE CIRCULATION

The project proposes bicycle facilities by implementing Class I multi-use paths and Class II bicycle lanes along the major transportation corridors, particularly in the northern portion of the project. Less formal trails are proposed to traverse the preserved open space areas. Pathways will lead to the proposed Foundation Regional Park in the southern portion of the community and a Class I bike path will connect through the proposed Lime Rock Valley Specific Plan to the El Dorado Trail.

5.6 TRANSIT

As described above, the project will provide bicycle and pedestrian connections to existing and planned bicycle and pedestrian facilities and will provide a 100 to 120 space park-n-ride lot. To accommodate possible future public transit service, transit stops and bus shelters may be provided within the on-site portions of Marble Valley Parkway and Marble Lake Boulevard near the intersection of Lime Rock Valley Road. Based on ridership data presented in the *El Dorado Hills Community Transit Needs Assessment and US 50 Corridor Transit Operations Plan, Final Report*, 41,760 annual commute trips are made by El Dorado Hills residents using El Dorado Transit Commuter Service. Residents of El Dorado Hills account for about 72 percent of boardings at the El Dorado Hills Park-n-Ride lot, which includes riders that park in the lot and riders that use other means to access the service (i.e., walk, bike, and drop-off).

Based on this information, about one annual commute trip is generated per El Dorado Hills resident, assuming a population of 42,100 (2010 Census) in El Dorado Hills. Therefore, the project's 3,236 dwelling units could result in demand of about 8,400 annual commute trips (assuming a household population of 2.6 persons), or about 32 commute trips per weekday.

DRAFT

6.0 CUMULATIVE CONDITIONS

6.1 TRAVEL DEMAND FORECASTS

For this project, the El Dorado County model was utilized to develop forecasts in the study area. The El Dorado County model has a base year of 2010 and a forecast year of 2035 (Version EDC_CAT_03_2014) with an updated forecast year based on a 75/25 growth allocation scenario, which allocates a 75 percent of growth to the Community Regions and urban areas and 25 percent in Rural Regions. However, as is standard practice with large area travel demand models, a thorough model review was completed and the model was refined to ensure that it produced reasonable results in the study area.

The following refinements were implemented in the study area:

- Added roadway network detail
- Updated land use to reflect 2012 conditions
- Refined the traffic analysis zones (TAZs) in order to get more refined loading of trips in the study area
- Updated network attributes in the study area to reflect existing conditions (e.g. verified roadway network speeds, number of lanes on the roadway, and roadway capacities to reflect existing conditions)
- Updated the future year roadway network in the study area to only reflect the SACOG Metropolitan Transportation Plan (MTP) constrained roadway network, which is consistent with the County's Capital Improvement Program (CIP)
- Updated the future land use information to reflect approved and reasonably foreseeable projects in the study area
- Added peak hour assignment functionality

Specific information related to the model's performance is described below:

6.1.1 BASE YEAR MODEL VALIDATION

Before any model can be applied for use in a major specific plan application, it must first satisfy specific validation criteria identified by Caltrans, the Federal Highways Administration (FHWA), and the California Transportation Commission (CTC). These criteria were developed to ensure that a model is developed

such that it can accurately forecast existing conditions based on land use and roadway network information, which improves the model's ability to accurately forecast future conditions. The state-of-the-practice for developing defensible forecasts for changes in the roadway network and/or changes in proposed land use is to use a valid base year model.

The first step of any model validation is to ensure that the model generally produces similar results to existing counts. Please note that, since the model is being used to generate AM peak hour and PM peak hour forecasts, the model must be valid at our study facilities for both time periods.

Key metrics for model validation guidelines are described below:

- The volume-to-count ratio is computed by dividing the volume assigned by the model and the actual traffic count for individual roadways (or intersections). The volume-to-count ratio should be less than 10%.
- The deviation is the difference between the model volume and the actual count divided by the actual count. Caltrans provides guidance on the maximum allowable deviation by facility type (e.g. lower-volume roadways can have a higher deviation than higher-volume roadways). 75% of the study facilities should be within the maximum allowable deviation.
- The correlation coefficient estimates the correlation between the actual traffic counts and the estimated traffic volumes from the model. The correlation coefficient should be greater than 0.88.
- The percent Root Mean Square Error (RMSE) is the square root of the model volume minus the actual count squared divided by the number of counts. It is a measure similar to standard deviation in that it assesses the accuracy of the entire model. The RMSE should be less than 40%.

The model validation statistics are summarized in Table 11. As shown in Table 11, the model meets or exceeds the identified model validation statistics in the study area. As such, the model is deemed appropriate for use in this assessment.

- Cumulative No Project – Corresponds to a 2035 No Project Cumulative horizon that accounts for planned (and funded) roadway improvements, land use growth consistent with the 2004 General

El Dorado County model was used to develop AM and PM peak hour forecasts for the following scenarios: Dorado County Department of Transportation as the lead agency are identified in Table 12. The validated Summaries) and SACOG's MTP/SCS (Appendix A1: MTP/SCS Project List). All relevant projects with the El Dorado County Department of Transportation as the lead agency are identified in Table 12. The validated is primarily based on El Dorado County's CIP (Section 8.1 – west Slope Road/Bridge Individual Project that are planned to occur prior to year 2035 and are included in the cumulative analysis. This information Table 12 below describes capacity-enhancing improvements to roadway facilities in the project study area updated to include only roadway improvements consistent with the SACOG's MTP and the County's CIP. All modifications incorporated into the validated Base Year model were incorporated into the future year (2035) travel demand forecasting model. Additionally, as previously mentioned, the model was also updated to include only roadway improvements consistent with the SACOG's MTP and the County's CIP.

6.1.2 FUTURE (YEAR 2035) MODELING ASSUMPTIONS

Source: Fehr & Peers, 2014

Metric	Model Validation	Maximum Allowable Deviation
AM Peak Hour – 114 Count Locations		
Model/Count Ratio	1.04	between 0.90 and 1.10
Percent Within Caltrans Maximum Deviation	85%	> 75%
Percent Root Mean Square Error	24%	> 40%
Correlation Coefficient	0.98	> 0.88
PM Peak Hour – 114 Count Locations		
Model/Count Ratio	1.06	between 0.90 and 1.10
Percent Within Caltrans Maximum Deviation	86%	> 75%
Percent Root Mean Square Error	21%	> 40%
Correlation Coefficient	0.98	> 0.88

TABLE 11: TRAVEL DEMAND FORECASTING MODEL SUB AREA VALIDATION

Plan, and with approved and reasonably foreseeable projects in the study area, including the following:

- Bass Lake Hills Specific Plan
- Cameron Estates
- Carson Creek Specific Plan
- Dixon Ranch
- Lime Rock Valley Specific Plan
- Promontory
- Rancho Dorado
- Ridgeview
- San Stino Residential Project
- Serrano
- Tilden Park
- Valley View Specific Plan
- Central El Dorado Hills Specific Plan

Please note that this scenario assumes the allowable development levels based on the 398-lot Marble Valley Master Plan, which was previously approved in 1998.

- Cumulative Plus Proposed Project – Includes similar assumptions to the Cumulative No Project scenario, but incorporates buildout of the Proposed Project and associated roadway network.

For each scenario listed above, roadway segment and intersection turning movement volumes were pulled directly from the scenario-specific models and adjusted. Consistent with state-of-the-practice travel demand forecasting application, model error was corrected using the methodologies identified in the National Cooperative Highway Research Program Report 255 (Transportation Research Board, 1982) using the “difference method,” which adds the forecasted growth in traffic volume to existing roadway segment and intersection counts.

Figures 7 and 8 present AM and PM peak hour traffic volume forecasts for cumulative conditions without and with the proposed project, respectively.

TABLE 12: CAPACITY-ENHANCING ROADWAY IMPROVEMENTS (ASSUMED COMPLETION BY 2035)

Project Name	Project Description	Estimated Completion
Bass Lake Road Frontage Improvements	Perform roadway operational improvements on Bass Lake Road constructed by Silver Springs development.	By 2020
Bass Lake Road Improvements - Phase 1A	Widen and reconstruct Bass Lake Road from US 50 to Hollow Oak Road to 2-lane divided road with 4-foot shoulders and bicycle/pedestrian paths. Includes an 8-foot median, sidewalk, and bike lane from Hollow Oak Road to US 50; median improvements only from Hollow Oak Road to Serrano Parkway; improvements of park-and-ride lot with frontage road improvement to Old Bass Lake Road and Tierra de Dios. (See ELD19225/CIP#GP166 for Phase 1B). CIP#66109	By 2035
Bass Lake Road Widening	Widen Bass Lake Road from US 50 to Silver Springs Pkwy to accommodate 4 lanes of traffic (divided), curb, gutter, and sidewalk. (See ELD19224 for Phase 1A)	By 2035
Country Club Drive – Silva Valley Parkway to "Old Valley Parkway"	Construct new 2-lane road north of existing Tong Rd from Silva Valley Pkwy to the "Old Lincoln Hwy". This project is the first half of the ultimate project to connect Silva Valley Pkwy to Bass Lake Rd and provide parallel capacity to US 50. CIP#71335	By 2020
Country Club Drive Extension – Bass Lake Road to Silver Dove Road	Construct 2-lane extension of Country Club Drive from Bass Lake Road to Silver Dove Road. Roadway includes 6-foot paved shoulders and new intersection at Bass Lake Road. (Curb, gutter, and sidewalk may be included.) CIP#GP124	By 2035
Country Club Drive Extension - Silver Dove to west end of Bass Lake Hills	Construct new 2-lane extension of Country Club Drive from Silver Dove Road to the west end of Bass Lake Hills Specific Plan boundary for future connection to Silva Valley Parkway. Project includes 6-foot paved shoulders. (Curb, gutter, and sidewalk may be included). CIP#GP125	By 2035
El Dorado Hills Boulevard / Francisco Drive – Realignment	Realign existing El Dorado Hills Boulevard / Francisco Drive / Britany Way intersection and approach roadways to result in a new 4-way intersection with extensions and signal installation. Northern portion of El Dorado Hills Boulevard (at this intersection) will become new minor traffic way, and current Francisco Drive between El Dorado Hills Boulevard and Green Valley Road will become new major traffic way. CIP#72332	By 2035
El Dorado Hills Boulevard Widening - Lassen Lane to Park Drive	Widen El Dorado Hills Boulevard from Lassen Lane to Park Drive from 4 to 5 lanes (divided) by adding a third southbound lane. Project includes curb, gutter, and sidewalk. CIP#GP183	By 2035
Green Valley Rd Widening - Francisco to Salmon Falls	Widen Green Valley Rd from Francisco Dr to Salmon Falls Rd to 4-lanes divided with curb, gutter, and sidewalk. CIP#GP178	By 2035
Green Valley Road	Widen: 4-lanes from Salmon Falls Rd. east to Deer Valley Rd.	By 2035

TABLE 12: CAPACITY-ENHANCING ROADWAY IMPROVEMENTS (ASSUMED COMPLETION BY 2035)

Project Name	Project Description	Estimated Completion
Green Valley Road Widening - County Line to Francisco Drive	Construct a second eastbound through lane from the commercial area near Sophia Parkway intersection to Francisco Drive with traffic signal installation at the Green Valley Road/Browns Ravine/Miller Road intersection. Also add a second westbound lane from Francisco Drive to the commercial area near the Sophia Parkway intersection.	Completed
Latrobe Road Widening - Golden Foothill to Investment	Widen Latrobe Rd from Golden Foothill Pkwy (south end) to Investment Blvd from 2-lanes undivided to 4-lanes divided with curb, gutter, and Class II bike lanes; modify signal at Investment Blvd. CIP#72350	By 2035
Latrobe Road	Widen: 6 lanes (divided with 4-foot shoulders) from White Rock Rd. to Carson Creek (Sunset Ln.).	By 2035
Latrobe Rd / White Rock Rd Connector (New Road)	New connector road from the El Dorado Hills Business Park to White Rock Rd west of Four Seasons/Stonebriar intersection; Phase 1 to perform route alignment study and prepare PSR; Phase 2 will include environmental, design and construction; may require coordination with Sacramento County, City of Folsom, Southeast Connector JPA and area developers. CIP#66116	By 2035
Saratoga Wy Ext - Phase 1	Construct new 2-lane arterial to extend Saratoga Wy from current terminus near Finders Wy to Sacramento County Line; includes median, 6-ft shoulders, right-turn pocket onto Finders Way, asphalt path, drainage system, environmental clearance and secure ROW for future 4-lane road from County Line to El Dorado Hills Blvd. CIP71324 (Phase 2 CIP#GP147 - See ELD19234 in MTP.)	By 2035
Saratoga Wy. (Phase 2)	Widen: 4 lanes from the Sacramento/El Dorado County line to El Dorado Hills Blvd. Includes: full curb, gutter, and sidewalk. (See ELD16010 for Phase 1)	By 2035
Silva Valley Pkwy Widening from Entrada	Widen Silva Valley Pkwy (2 to 4 lanes) from Entrada Dr to 1000 feet south of Oak Meadow Elem School; includes sidewalk, bike lanes and left-turn storage for school entrance. CIP#72370	By 2020
Silva Valley Pkwy / Golden Eagle Ln - Signalization	Signalize intersection at Silva Valley Pkwy and Golden Eagle Ln (Silva Valley Elementary School). CIP#GP182	By 2035

TABLE 12: CAPACITY-ENHANCING ROADWAY IMPROVEMENTS (ASSUMED COMPLETION BY 2035)

Project Name	Project Description	Estimated Completion
Silver Springs Parkway to Bass Lake Road	It is anticipated that Silver Springs Parkway will be built as a two-lane standard divided roadway with shoulders. It is planned to realign Bass Lake Road south of Green Valley Road through the proposed Silver Springs subdivision, which is west of the existing Bass Lake Road. The new road is named Silver Springs Parkway. That development is responsible for building Silver Springs Parkway through their development. There is a portion of the new alignment that falls to the south of the Silver Springs development that must also be built to connect the new road to the existing Bass Lake Road to the south.	By 2020
Silver Springs Parkway to Green Valley Road	Construct new Silver Springs Parkway through the Silver Springs Development from Bass Lake Road to Green Valley Road and install signal at Silver Springs Parkway and Green Valley Road intersection. Connect to realigned Bass Lake Road north of Bass Lake.	By 2020
Sophia Parkway	Widen: 4 lanes (divided) from Alexandria Rd. to Empire Rancho Rd. at the County Line.	By 2035
US 50 / Bass Lake Road (Phase 2)	Add Auxiliary Lane: WB on US 50 between Bass Lake Rd. and Cambridge Rd. interchanges. Includes: additional ramp, road widening (Phase 2) (See ELD19182 for Phase 1).	By 2035
US 50 / Cambridge Road (Phase 2)	Add Auxiliary Lane: on US 50 EB between Cameron Park Dr. and Bass Lake Rd. interchanges. Includes bridge widening to add two lanes and ramp widening (Phase 2) (See ELD19181 for Phase 1).	By 2035
US 50 Aux Lane WB - El Dorado Hills to Empire Ranch	Widen US 50 and add auxiliary lane to westbound US 50 connecting the El Dorado Hills Blvd/Latrobe Rd interchange to the future Empire Ranch Rd interchange located in the City of Folsom; (City of Folsom will construct the EB aux lane.) Timing of construction to be concurrent with or after the El Dorado Hills Blvd Interchange (ELD15630/CIP71323) or Empire Ranch Interchange. CEQA/NEPA cleared through the Empire Ranch Interchange environmental document. CIP#53115	By 2035
US 50 Auxiliary Lane Eastbound – Cambridge to Ponderosa	Construct eastbound auxiliary lane on US 50 between Cambridge Rd and Ponderosa Rd interchanges. CIP GP150	By 2035
US 50 Bus / Carpool Lanes	Bus/Carpool Lanes – Phase 3: US 50-Ponderosa Road to Greenstone Road.	By 2035

TABLE 12: CAPACITY-ENHANCING ROADWAY IMPROVEMENTS (ASSUMED COMPLETION BY 2035)

Estimated Completion	Project Description	Project Name
Completed	<p>Phase 1 (El Dorado Hills to Bass Lake Grade) - Add HOV lanes in median of US 50 between El Dorado Hills Blvd/Latrobe Rd and Bass Lake Rd interchanges (PM 0.5 to PM 4.2 eastbound and PM 0.9 to PM 2.9 westbound); includes extension of EB truck climbing lane from Latrobe Rd to base of Bass Lake Grade, median widenings of Clarksville Rd and Bass Lake Rd undercrossings, and replacement of EDH Blvd undercrossings including EB off-ramp. (See ELD19287 for Phase 2A, ELD19290 for Phase 2B and ELD19289 for future unfunded Phase 3 in the MTP). Emission Benefits in kg/day: ROG 27, NOx 28, PM10 15, CO 303. CIP#53110</p>	<p>US 50 HOV Lanes - Phase 1</p>
Completed	<p>Phase 2A (Bass Lake Rd to Cameron Park Dr) - Add HOV lanes in median of US 50 between Bass Lake Rd and Cameron Park Dr Interchanges. PA&ED completed by Caltrans. Caltrans advancing project design through Cooperative Agreement with the County. Intergovernmental Agreement between County and Shingler Springs Band of Miwok Indians for funding (coded as Local Agency Funds). (Emission Benefits in kg/day: ROG, 20 NOx, 12 PM10.) (See ELD19211/CIP53113 for Phase 1, ELD19290/CIP53122 for Phase 2B and ELD19289/CIP#53116 for future unfunded Phase 3 in the MTP). CIP#53113</p>	<p>US 50 HOV Lanes - Phase 2A</p>
By 2035	<p>Phase 2B (Cameron Park Dr to Ponderosa Rd.) - Add HOV lanes in median of US 50 between Cameron Park Dr. and Ponderosa Rd. interchanges. PA&ED completed by Caltrans. Caltrans advancing project design through Cooperative Agreement with the County. Intergovernmental Agreement between County and Shingler Springs Band of Miwok Indians for funding (coded as Local Agency Funds). (See ELD19211/CIP53113 for Phase 1, ELD19290/CIP53122 for Phase 2B and ELD19289/CIP53116 for future unfunded Phase 3 in the MTP). CIP53113</p>	<p>US 50 HOV Lanes - Phase 2B</p>
By 2035	<p>Construct new westbound aux lane within median of US 50 between Silva Valley Pkwy and Empire Ranch Rd future new interchanges; requires coordination with Silva Valley I/C (ELD15610/CIP#71328), El Dorado Hills I/C (ELD15630/CIP71323) and Empire Ranch I/C (City of Folsom project). CIP#53120</p>	<p>US 50 Mainline Widening at El Dorado Hills</p>
By 2035	<p>Interchange Improvements: this phase includes detailed study to determine complete improvements needed; Phase 1 may include ramp widening, road widening, signals, and WB auxiliary lane between Bass Lake and Silva Valley interchanges; Phase 1 assumes bridge replacement. (See ELD19217 for Phase 2). CIP#71330</p>	<p>US 50 / Bass Lake Rd Interchange - Phase 1</p>

TABLE 12: CAPACITY-ENHANCING ROADWAY IMPROVEMENTS (ASSUMED COMPLETION BY 2035)

Estimated Completion	Project Description	Project Name
By 2035	Interchange Improvements: this phase includes widening existing EB and WB on-/off-ramps; addition of new WB on-ramp; reconstruction of local intersections; and installation of traffic signals at EB and WB ramp terminal intersections; preliminary engineering for Phase 2 to be performed under Phase 1. (See ELD19218 for Phase 2) CIP#71332	US 50 / Cambridge Rd. Interchange – Phase 1
By 2020	Interchange Improvements: this project includes detailed study to identify capacity improvement alternatives and selection of preferred alternative; assumes reconstruction of US 50 bridges to widen Cameron Park Dr. to 8 lanes under the overcrossing; road and ramp widening. CIP#72361	US 50 / Cameron Park Dr. Interchange Improvements
By 2020	Reconstruct eastbound diagonal on-ramp and eastbound loop off-ramp for the ultimate configuration; add a lane to northbound El Dorado Hills Blvd under the overpass (eliminates merge lane and improves traffic flow from the eastbound loop off-ramp); eastbound diagonal on-ramp will be metered and have an HOV bypass. Project split from ELD15630 (CIP#71323).	US 50 / El Dorado Hills Blvd Interchange Eastbound Ramps
Completed	Interchange Improvements: includes signalization and widening of existing ramps. (See ELD19272 for Phase 2). CIP#71347	US 50 / El Dorado Rd Interchange - Phase 1
Ongoing	Interchange Improvements: this phase involves construction of left and right turn lanes and additional through traffic lanes in all approaches to the interchange. (See ELD19178/CIP#71347 for Phase 1). CIP#71376	US 50 / El Dorado Rd Interchange - Phase 2
Ongoing	Interchange Improvements: this final phase constructs new WB off-ramp undercrossing, improves WB on-/off-ramps and widens El Dorado Hills Blvd. (Coordinates with ELD19215/CIP#53120, ELD19273/CIP#53115, ELD19173/CIP#71340, and ELD19345). CIP#71323	US 50 / El Dorado Hills Blvd Interchange – Final Phase
By 2035	Construct ped/bike overcrossing over US 50 just east of El Dorado Hills Blvd. Interchange; includes a Class 3 mixed use path; construction and ROW acquisition for 10-ft wide sidewalk and adjacent retaining walls, barriers, railings, and landscape replacement included with CIP#71323 (see ELD15630). CIP#71340.	US 50 / El Dorado Hills Blvd Pedestrian Overcrossing
Ongoing	New Interchange: Phase 1 includes US 50 on-/off-ramps, overcrossing, and US 50 aux lanes. (See ELD19291/CIP#71345 for Phase 2). CIP#71328	US 50 / Silva Valley Pkwy Interchange - Phase 1
By 2035	Final phase of new interchange: construction of eastbound diagonal and westbound loop on-ramps to US 50. (See ELD15610/CIP#71328 for Phases 1). CIP#71345	US 50 / Silva Valley Pkwy Interchange - Phase 2 (Connector Segment)

TABLE 12: CAPACITY-ENHANCING ROADWAY IMPROVEMENTS (ASSUMED COMPLETION BY 2035)

Project Name	Project Description	Estimated Completion
White Rock Rd Widening - Manchester to County Line (Connector Segment)	Widen White Rock Rd from 2 to 4 lanes, divided, from Manchester Dr east to Sacramento County Line. CIP#GP137	By 2035
White Rock Rd Widening - Monte Verde to US 50 / Silva Valley (Connector Segment)	Widen White Rock Rd from 2-lanes undivided to 4 lanes divided, from Monte Verde Dr east to new future US 50/Silva Valley Pkwy Interchange (ELD15610/CIP71328); includes curb, gutter, sidewalk, and Class II bike lanes. ROW costs include acquisition for ultimate 6-lane facility (see CIP#GP152/ELD19235 in MTP). CIP#72374	By 2035
White Rock Rd Widening - Latrobe to Monte Verde (Connector Segment)	Widen White Rock Rd (2 lanes undivided to 4 lanes divided) from Post St to the culvert east of Monte Verde Dr; install new traffic signal at White Rock Rd/Windfield Wy; includes curb, gutter, sidewalk, and Class II bike lanes. CIP#72372	By 2020
White Rock Rd (Connector Segment)	Widen: 6 lanes (divided) from Latrobe Rd. to US 50 / Silva Valley Pkwy. Interchange.	By 2035
White Rock Rd / Post St - Signalization (Connector Segment)	Signalize intersection at White Rock Rd and Post St in El Dorado Hills. CIP#73310	By 2035

6.2 PEAK HOUR VEHICLE LEVEL OF SERVICE

6.2.1 INTERSECTIONS

Analysis results, which are presented in Table 13, indicate that many of the study intersections, which are stop controlled, will operate unacceptably with increased traffic from build-out of the proposed project added to cumulative background traffic. Traffic generated by the project result in potential impacts at the following locations:

- Bass Lake Road/Serrano Parkway (Intersection 1) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours.
- Bass Lake Road/Hollow Oak Drive (Intersection 2) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours.
- Bass Lake Road/Old Bass Lake Road (Intersection 3) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours.
- Bass Lake Road/Country Club Drive (Intersection 4) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours.
- Bass Lake Road/US 50 westbound ramps (Intersection 5) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection will operate unacceptably at LOS E in the AM peak hour and LOF F in the PM peak hour without the project. According to established significance criteria, the project is projected to “significantly

worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours.

- Bass Lake Road/US 50 eastbound ramps (Intersection 6) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection will operate unacceptably at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours.
- Marble Valley Parkway/Marble Mountain Road (Intersection 7) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection will operate acceptably at LOS D without the project during the AM and PM peak hours. The project results in unacceptable (LOS F) conditions during the AM and PM peak hours.
- Marble Valley Parkway/Marble Ridge Road (Intersection 8) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection will operate acceptably at LOS C during the AM peak hour and unacceptably at LOS E without the project during the PM peak hour. The project will also result in unacceptable (LOS F) conditions during the AM peak hour and according to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the PM peak hour.
- Cambridge Road/Country Club Drive (Intersection 9) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours.
- Cambridge Road/Knollwood Drive (Intersection 10) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours.
- Cambridge Road/US 50 westbound ramps (Intersection 11) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours.

Intersection	LOS Target	Control	Cumulative Conditions (LOS / Delay)	Cumulative Plus Project (LOS / Delay)
1. Bass Lake Road/Serrano Parkway	E	AWSC	F / 112	F / 70
2. Bass Lake Road/Hollow Oak Drive	E	SSSC	F / < 180	F / < 180
3. Bass Lake Road/Old Bass Lake Road	D	SSSC	F / < 180	F / < 180
4. Bass Lake Road/Country Club Drive	D	SSSC	F / < 180	F / < 180

6. Bass Lake Road/US EB 50 Ramps	D	Signal	F / 107	F / 148
7. Marble Valley Road/ Marble Mountain Road	D	SSSC	D / 30	F / < 180
8. Marble Valley Road/ Marble Ridge Road	D	SSSC	C / 16	F / < 180

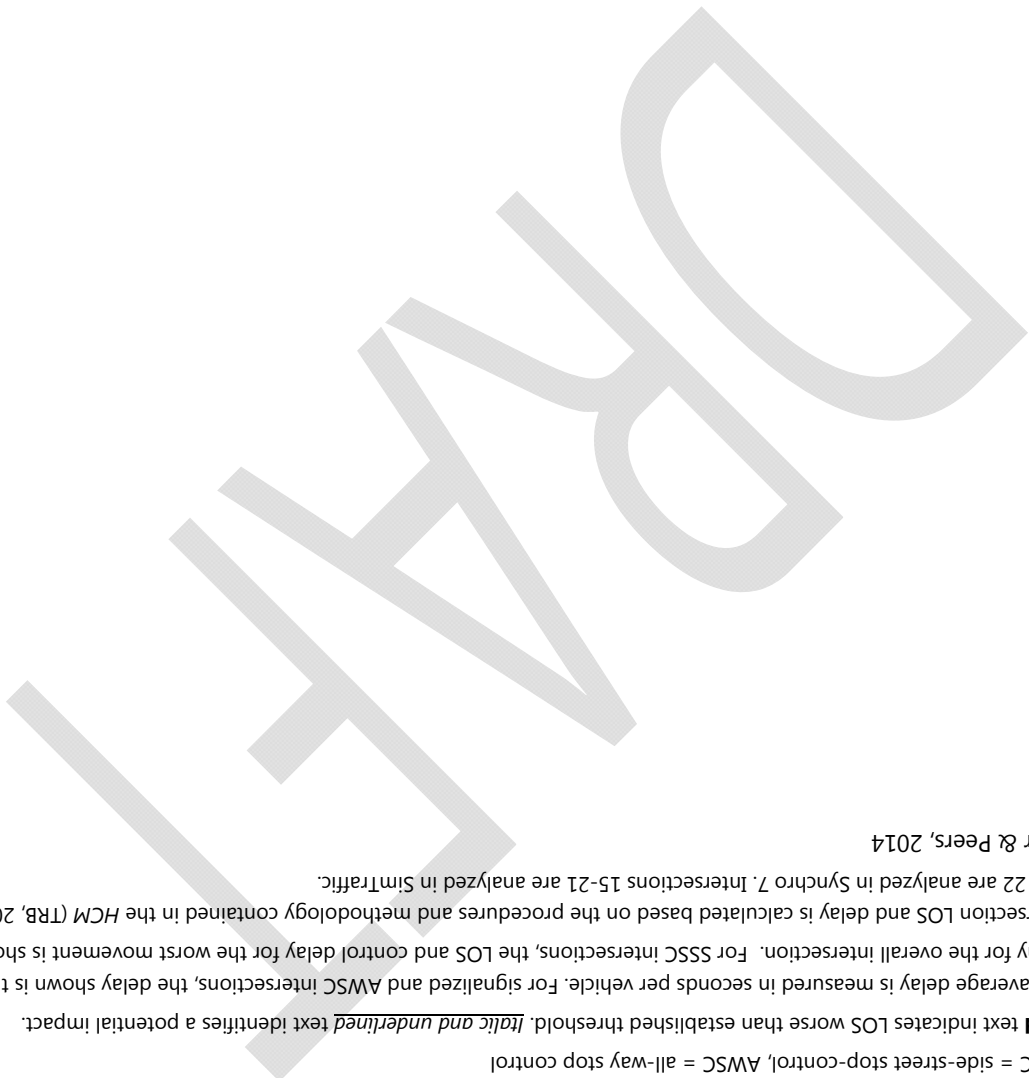

TABLE 13: INTERSECTION LOS AND DELAY – CUMULATIVE CONDITIONS

- Cambridge Road/Flying C Road/Crazy Horse Road (Intersection 13) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours.
- El Dorado Hills Boulevard/Park Drive/Saratoga Way (Intersection 19) – This intersection will operate acceptably at LOS D during the AM peak hour and unacceptably at LOS F without the project during the PM peak hour. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the PM peak hour.
- Latrobe Road/Town Center Drive (Intersection 21) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours.

Source: Fehr & Peers, 2014

Note: SSSC = side-street stop-control, AWSC = all-way stop control. **Bold** text indicates LOS worse than established threshold. *Italic and underlined* text identifies a potential impact. The average delay is measured in seconds per vehicle. For signalized and AWSC intersections, the delay shown is the average control delay for the overall intersection. For SSSC intersections, the LOS and control delay for the worst movement is shown. Intersection LOS and delay is calculated based on the procedures and methodology contained in the HCM (TRB, 2000). Intersections 1-14 and 22 are analyzed in Synchro 7. Intersections 15-21 are analyzed in SimTraffic.

Intersection	LOS Target	Control	Cumulative Conditions (LOS / Delay)		Cumulative Plus Project (LOS / Delay)	
			AM	PM	AM	PM

TABLE 13: INTERSECTION LOS AND DELAY – CUMULATIVE CONDITIONS

6.2.2 ROADWAY SEGMENTS

Analysis results, which are presented in Table 14, indicate that all study roadway segments except for one will operate acceptably under cumulative conditions, due primarily to the capacity increasing roadway project included in the County's CIP, which are documented in Table 12. Without the project, the segment of Cameron Park Drive between Alhambra Drive and Oxford Road would operate unacceptable (LOS F) conditions during the PM peak hour. According to established significance criteria, the project is projected to "significantly worsen" conditions, since it would add more than 10 trips to the roadway segment during the PM peak hour.

Notes: ¹LOS at this location is C or better.

²Cambridge Road between Country Club Drive and Oxford Road is allowed to operate at LOS F (maximum V/C/ ratio of 1.07) until 2018 per County standard

³Durock Road/Cameron Park Drive between Coach Lane and Robin Lane is allowed to operate at LOS F (maximum V/C ratio of 1.11) until 2018 per County standard.

Volume-to-Capacity ratio and LOS is based on the HCM 2010 peak hour level of service thresholds.

Bold text indicates LOS worse than established threshold. *Italic and underlined* text identifies a potential impact.

Source: Fehr & Peers, 2014

6.2.3 FREEWAY FACILITIES

Analysis results, which are presented in Table 15, indicate that most of the study freeway facilities will operate at LOS D or better under cumulative conditions. One weave section will operate at LOS E. The capacity increasing projects from the County's CIP, which are documented in Table 12, include many projects that will add capacity of US 50, increase east/west parallel capacity, and add new interchange connections to US 50 that will provide alternatives to the existing US 50/El Dorado Hills Boulevard interchange. The following lists some of the more significant transportation improvements in the US 50 corridor:

Interchange Projects

- US 50/El Dorado Hills Boulevard Interchange Improvements (final improvement phases)
- US 50/Silva Valley Parkway Interchange (new connection to US 50)
- US 50/Empire Ranch Road Interchange (new connection to US 50)
- US 50/Bass Lake Road Interchange Upgrade
- US 50/Cambridge Road Interchange Upgrade

Mainline Projects

- Westbound US 50 interchange-to-interchange auxiliary lane (Bass Lake Road to Silva Valley Parkway)
- Westbound US 50 auxiliary lane (Silva Valley Parkway to Empire Ranch Road)
- Westbound US 50 interchange-to-interchange auxiliary lane (Silva Valley Parkway to El Dorado Hills Boulevard)
- Eastbound US 50 interchange-to-interchange auxiliary lane (El Dorado Hills Boulevard to Silva Valley Parkway)
- Westbound US 50 interchange-to-interchange auxiliary lane (Cambridge Drive to Bass Lake Road)
- Eastbound US 50 interchange-to-interchange auxiliary lane (Bass Lake Road to Cambridge Drive)

Arterial Roadway Projects

- Country Club Drive Extension from Bass Lake Road to Silva Valley Parkway
- Saratoga Way Extension from El Dorado Hills Boulevard to Iron Point Road
- Extension of Empire Ranch Road from US 50 to White Rock Road
- Latrobe Road Connector (new roadway between Latrobe Road and White Rock Road)

Figure 11 compares existing conditions on US 50 to US 50 with the interchange and mainline projects listed above. Figure 12 shows peak hour US 50 mainline and ramp volumes under cumulative conditions. About 11 percent of project trips will have an origin/destination in Rancho Cordova and other areas to the west, including unincorporated Sacramento County and the City of Sacramento.

The westbound weaving sections between Silva Valley Parkway and El Dorado Hills Boulevard and between El Dorado Hills Boulevard and Empire Ranch Road will operate at LOS E during the AM peak hour without or with the proposed project, based on the HCM weave analysis method. However, analysis of

the weaving section based on the Leisch method (preferred by Caltrans District 3) indicates that these weave sections would operate at LOS C during the same period. The westbound weaving sections between El Dorado Hills Boulevard and Empire Ranch Road will operate at LOS F during the AM peak hour with the proposed project, based on the HCM weave analysis method.

6.3 PEDESTRIAN AND BICYCLE CIRCULATION

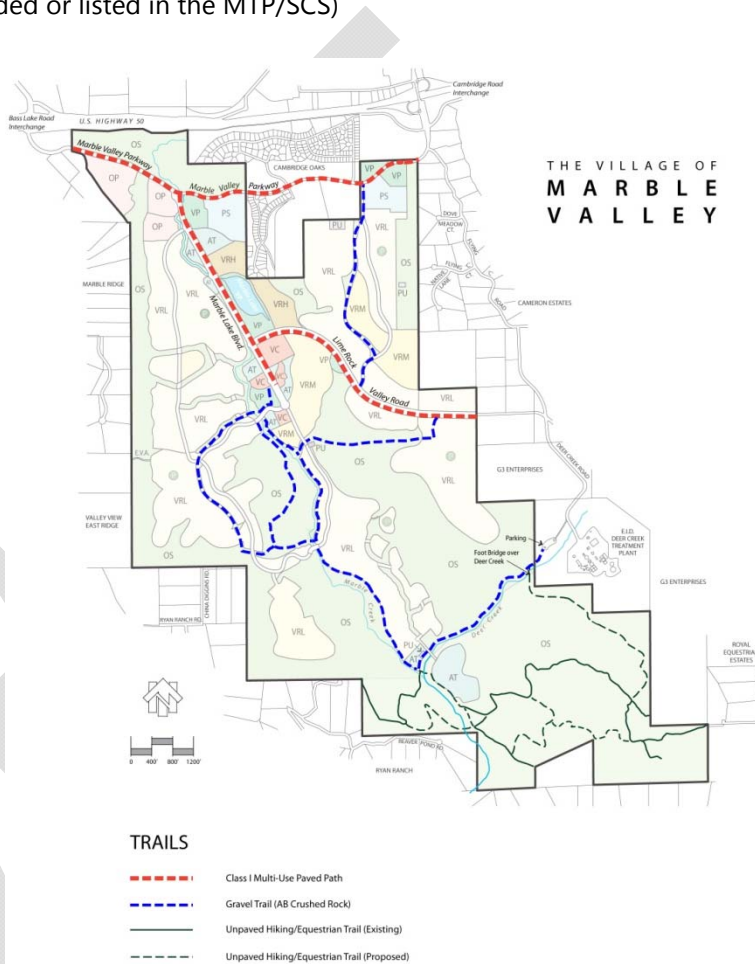

Bicycle network improvements are planned within the study area. Figure 5 identifies planned bikeways presented in the *El Dorado Bicycle Transportation Plan, 2010 Update* and the *Sacramento Area Council of Governments (SACOG) Metropolitan Transportation Plan/Sustainable Communities Strategy (MTP/SCS) for 2035*. The following are planned improvement projects:

- El Dorado Hills Class I bike path - SMUD Corridor: Design and construct a Class I bike path between El Dorado Hills Boulevard and Silva Valley Parkway within the powerline easement operated by the Sacramento Municipal Utility District (SMUD). A portion of this project has been constructed between Silva Valley and New York Creek,
- Latrobe Road Class II bike lanes from Investment Boulevard to Deer Creek/SPTC
- Old Bass Lake Road – El Dorado Hills Boulevard to Bass Lake Road Connection, Phase 1: Use existing roadway as Class I path from Tong Road to Old Bass Lake Road
- Saratoga Way Extension Class II bike lanes included in extension of Saratoga Way from Finders Way to County Line. (Alternatively construct a Class I bike path prior to construction of extension of Saratoga Way to Iron Point Road) An informal trail exists connecting these roadways,
- Bass Lake Road Class II bike lanes from Green Valley Road to US 50
- Bike path parallel to US 50 on the north side – El Dorado Hills Boulevard to Bass Lake Road Connection, Phase 2: Connect Silva Valley Road to El Dorado Hills Village Center Shopping Center. The Central El Dorado Hills Specific Plan will implement a portion of this bike path.
- El Dorado Hills Boulevard bike lanes, Phase 1: Saratoga Way to Governor Drive/St. Andrews
- El Dorado Hills Boulevard bike path, Phase 2: Utilizing an existing golf cart undercrossing of Serrano Parkway, extend the bike path from the current terminus at Serrano Parkway to Raley's Center. The Central El Dorado Hills Specific Plan will implement this improvement.
- El Dorado Hills Boulevard to Bass Lake Connection, Phase 1; Class III bike route on Tong Road, Class III bike route on Old Bass Lake Road.
- Green Valley Road Class II bike lanes from Francisco Drive to Pleasant Grove Middle School
- Harvard Way bike path from Clermont Road to El Dorado Hills Boulevard
- Silva Valley Parkway bike lanes from the new connection with White Rock Road to Green Valley Road
- SPTC/El Dorado Trail Class I bike path from Latrobe Road to County Line

- Class I bike path and US 50 Undercrossing or overcrossing between the El Dorado Hills Town Center and El Dorado Hills Village Center (not fully funded or listed in MTP/SCS). As outlined below, the Central El Dorado Hills Specific Plan proposes to locate the overcrossing of US 50 adjacent to the Village Park with, connecting the planned bike path north of US 50 to the El Dorado Hills Town Center.
- Class I bike path within the SMUD power line easement between El Dorado Hills Boulevard and Sophia Parkway (not fully funded or listed in the MTP/SCS)

The project proposes a Class I multi-use path on Marble Valley Parkway, Marble Lake Boulevard, and Lime Rock Valley Road. In addition, the project proposes a network of gravel trails and unpaved hiking/equestrian trails integrating with existing trails. The image to the right shows proposed bicycle facilities and trails.

6.4 TRANSIT

As described above, the project will provide bicycle and pedestrian connections to existing and planned bicycle and pedestrian facilities and will provide a 100 to 120 space park-n-ride lot. To accommodate possible future public transit service, transit stops and bus shelters may be provided within the on-site portions of Marble Valley Parkway and Marble Lake Boulevard near the intersection of Lime Rock Valley Road. Based on ridership data presented in the *El Dorado Hills Community Transit Needs Assessment and US 50 Corridor Transit Operations Plan, Final Report*, 41,760 annual commute trips are made by El Dorado Hills residents using El Dorado Transit Commuter Service. Residents of El Dorado Hills account for about 72 percent of boardings at the El Dorado Hills Park-n-Ride lot, which includes riders that park in the lot and riders that use other means to access the service (i.e., walk, bike, and drop-off).

Based on this information, about one annual commute trip is generated per El Dorado Hills resident, assuming a population of 42,100 (2010 Census) in El Dorado Hills. Therefore, the project's 3,236 dwelling units could result in demand of about 8,400 annual commute trips (assuming a household population of 2.6 persons), or about 32 commute trips per weekday.

7.0 IMPACT STATEMENTS AND MITIGATION MEASURES

Project impacts were determined by comparing conditions with the project to conditions without the project in accordance with the established significance criteria presented in Section 4.2.

7.1 EXISTING PLUS PROJECT

Analysis results, which are presented in Table 16, indicate that the addition of the project would exacerbate unacceptable operations at three intersection and result in unacceptable operation at nine intersections. The following discusses these impacts and associated mitigation:

7.1.1 INTERSECTIONS

Impacts

- Impact 1 - Bass Lake Road/Serrano Parkway (Intersection 1) – This intersection operates acceptably at LOS D and B during the AM and PM peak hours, respectively, without the project. The project results in unacceptable (LOS F) conditions during the AM peak hour. **This is a significant impact.**
- Impact 2 - Bass Lake Road/Country Club Drive (Intersection 4) – This intersection is located in the County's Rural Region and is subject to the LOS D significance threshold. This intersection operates unacceptably at LOS F without the project during the AM peak hour and acceptably at LOS C during the PM peak hour. According to established significance criteria, the project is projected to "significantly worsen" conditions, since it would add more than 10 trips to the intersection during the AM peak hour operations. The project would also result in unacceptable (LOS F) conditions during the PM peak hour. **This is a significant impact.**
- Impact 3 - Bass Lake Road/US 50 westbound ramps (Intersection 5) – This intersection is located in the County's Rural Region and is subject to the LOS D significance threshold. This intersection operates acceptably at LOS B and LOS C during the AM and PM peak hours, respectively, without the project. The project results in unacceptable (LOS F) conditions during the AM and PM peak hours. Poor operation at this intersection will result in vehicle queuing on the westbound off ramp during the PM peak hour that could cause vehicles to spill back to the US 50 mainline, impacting mainline operations. **This is a significant impact.**

- Impact 4 - Bass Lake Road/US 50 eastbound ramps (Intersection 6) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection operates acceptably at LOS C during the AM peak hour and unacceptably at LOS F during the PM peak hour without the project. The project would also result in unacceptable (LOS F) conditions during the AM peak hour, and according to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the PM peak hour. Poor operation at this intersection will result in vehicle queuing on the eastbound off ramp during the PM peak hour that could cause vehicles to spill back to the US 50 mainline, impacting mainline operations. **This is a significant impact.**
- Impact 5 - Marble Valley Parkway/Marble Mountain Road (Intersection 7) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection operates acceptably at LOS A without the project during the AM and PM peak hours. The project results in unacceptable (LOS F) conditions during the AM and PM peak hours. **This is a significant impact.**
- Impact 6 - Marble Valley Parkway/Marble Ridge Road (Intersection 8) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection operates acceptably at LOS A without the project during the AM and PM peak hours. The project results in unacceptable (LOS F) conditions during the AM and PM peak hours. **This is a significant impact.**
- Impact 7 - Cambridge Road/Country Club Drive (Intersection 9) – This intersection operates acceptably at LOS E and C during the AM and PM peak hours, respectively, without the project. The project results in unacceptable (LOS F) conditions during the AM peak hour. **This is a significant impact.**
- Impact 8 - Cambridge Road/Knollwood Drive (Intersection 10) – This intersection operates unacceptably at LOS F during the AM peak hour and acceptably at LOS E during the PM peak hour without the project. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM peak hour. The project would also result in unacceptable (LOS F) conditions during the PM peak hour. **This is a significant impact.**
- Impact 9 - Cambridge Road/US 50 eastbound ramps (Intersection 12) – This intersection operates acceptably at LOS B and E during the AM and PM peak hours, respectively, without the project. The project results in unacceptable (LOS F) conditions during the AM and PM peak hours. **This is a significant impact.**
- Impact 10 - Cambridge Road/Flying C Road/Crazy Horse Road (Intersection 13) – This intersection operates acceptably at LOS B during the AM and PM peak hours without the project.

The project results in unacceptable (LOS F) conditions during the AM peak hour. **This is a significant impact.**

Impact 11 - El Dorado Hills Boulevard/Park Drive/Saratoga Way (Intersection 19) – This intersection operates acceptably at LOS D and C during the AM and PM peak hours, respectively, without the project. The project results in unacceptable (LOS F) conditions during the AM peak hour. **This is a significant impact.**

Impact 12 - Latrobe Road/Town Center Drive (Intersection 21) – This intersection operates acceptably at LOS C and E during the AM and PM peak hours, respectively, without the project. The project results in unacceptable (LOS F) conditions during the PM peak hour. **This is a significant impact.**

Mitigation

Mitigation 1 - Bass Lake Road/Serrano Parkway (Intersection 1) – A traffic signal has been installed at the Bass Lake Road/Serrano Parkway intersection as part of the realignment of Sienna Ridge Road, since existing conditions data was collected. Traffic signal control will result in acceptable LOS B operation during the AM and PM peak hours. With this improvement, this impact would be **less than significant.**

Mitigation 2 - Bass Lake Road/Country Club Drive (Intersection 4) – This intersection will be part of the planned widening of Bass Lake Road and the reconstruction of the US 50/Bass Lake Road interchange, which are included in the County's 10-year CIP. Implementation of the US 50/Bass Lake Road interchange reconstruction project, which has not been designed, would result in acceptable LOS C and B operation during the AM and PM peak hours, respectively, at the Bass Lake Road/Country Club Drive intersection with build-out of the proposed project. The following improvements would provide acceptable operation:

- Relocate Country Club Drive north of its current intersection with Bass Lake Road to improve intersection spacing with the interchange ramp intersections.
- Reconstruct US 50/Bass Lake Road interchange to provide a Type L-9 Configuration, which includes slip on- and off-ramps, southbound-to-eastbound and northbound-to-westbound loop on-ramps, and a four- to five-lane overcrossing.
- Provide traffic signal control at the Bass Lake Road/Country Club Drive (Intersection 4), Bass Lake Road/US 50 westbound ramps (Intersection 5) intersection and at the Bass Lake Road/US 50 eastbound ramps (Intersection 6) with coordinated traffic signal operation.

- Construct the Marble Valley Parkway connection (i.e., the two-lane connection that lies outside the project area) that will complete Marble Valley Parkway between Marble Lake Boulevard and Cambridge Road.

The project identified in the CIP describes reconstruction of the interchange at its current location, which would be a similar to the US 50/El Dorado Hills Boulevard interchange. An alternative approach, that should be considered, would relocate the interchange east of its current location, similar to the US 50/Silva Valley Parkway interchange. This approach would provide for a more flexible design, implementation phasing, and allow use of the current US 50 undercrossing for local access.

Implementation of this improvement would result in acceptable LOS D or better operations during the AM and PM peak hours. With this improvement, this impact would be **less than significant**.

The analysis of the project under existing conditions assumes that the entire project develops immediately. However, development of the proposed project is anticipated to occur over 20 or more years. Consequently, the phasing of offsite infrastructure improvement is not certain and will be influenced by the following factors:

- The rate and location of regional development
- The location of development within the project site
- The type of development within the project site
- The implementation of roadway improvement constructed by others

The project applicant should work collaboratively with El Dorado County to initiate programming studies to identify the scope of the ultimate interchange reconstruction, which will be used to guide phased implementation of at-grade improvements and interchange reconstruction to ensure consistency with General Plan Policy TC-Xf.

Since the project is included in the County's 10-year CIP, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards this improvement.

Mitigation 3 - Bass Lake Road/US 50 westbound ramps (Intersection 5) – This intersection will be part of the planned reconstruction of the US 50/Bass Lake Road interchange, which is included in the County's 10-year CIP. Implementation of Mitigation 2 would provide LOS B operation in the AM and PM peak hour at the Bass Lake Road/US 50 westbound

ramps with build-out of the proposed project. With this improvement, this impact would be **less than significant**.

Mitigation 4 - Bass Lake Road/US 50 eastbound ramps (Intersection 6) – This intersection will be part of the planned reconstruction of the US 50/Bass Lake Road interchange, which is included in the County's 10-year CIP. Implementation of Mitigation 2 would provide LOS C and D operation in the AM and PM peak hour at the Bass Lake Road/US 50 eastbound ramps with build-out of the proposed project. With this improvement, this impact would be **less than significant**.

Mitigation 5 - Marble Valley Parkway/Marble Mountain Road (Intersection 7) – This intersection will be part of the planned reconstruction of the US 50/Bass Lake Road interchange, which is included in the County's 10-year CIP. Implementation of Mitigation 2 would provide LOS A operation in the AM and PM peak hours with build-out of the proposed project. With this improvement, this impact would be **less than significant**.

Mitigation 6 - Marble Valley Parkway/Marble Ridge Road (Intersection 8) – This intersection will be part of the planned reconstruction of the US 50/Bass Lake Road interchange, which is included in the County's 10-year CIP. Implementation of Mitigation 2 would provide LOS A operation in the AM and PM peak hours with build-out of the proposed project. With this improvement, this impact would be **less than significant**.

Mitigation 7 - Cambridge Road/Country Club Drive (Intersection 9) – Implementation of the following improvements to the Cambridge Road/Country Club Drive intersection would result in acceptable LOS B and C operation during the AM and PM peak hours, respectively:

- Install traffic signal control
- Provide one left-turn lane and a shared through/right-turn lane on the northbound and southbound approaches
- Provide protected left-turn phasing on the northbound and southbound approaches

Implementation of this improvement would result in acceptable LOS E or better operations during the AM and PM peak hours. With this improvement, this impact would be **less than significant**.

The analysis of the project under existing conditions assumes that the entire project develops immediately. However, development of the proposed project is anticipated to occur over 20 or more years. Consequently, the phasing of offsite infrastructure improvement is not certain and will be influenced by the following factors:

- The rate and location of regional development

- The location of development within the project site
- The type of development within the project site
- The implementation of roadway improvement constructed by others

If constructed by others prior to residential development levels in the project site that would require this mitigation, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards this improvement. If not constructed by others, the applicant would be responsible for implementing this improvement consistent with General Plan Goal TC-X and supporting Policy TC-Xf to ensure that transportation improvements are implemented concurrent with approved residential development. If constructed by the applicant, the applicant would be subject to fee credit or reimbursement through the County's traffic impact mitigation fee program.

Mitigation 8 - Cambridge Road/Knollwood Drive (Intersection 10) – This intersection will be part of the planned Phase 1 improvements to the US 50/Cambridge Road Interchange, which are included in the County's 10-year CIP. Implementation of the following improvements to the Cambridge Road/Knollwood Drive intersection would result in acceptable LOS C and B operation during the AM and PM peak hours, respectively:

- Install traffic signal control
- Provide coordinated traffic signal operation with westbound off-ramp terminal intersection
- Provide one left-turn lane and a shared through/right-turn lane on the northbound and southbound approaches
- Provide protected left-turn phasing on the northbound and southbound approaches

Implementation of this improvement would result in acceptable LOS E or better operations during the AM and PM peak hours. With this improvement, this impact would be **less than significant**.

The analysis of the project under existing conditions assumes that the entire project develops immediately. However, development of the proposed project is anticipated to occur over 20 or more years. Consequently, the phasing of offsite infrastructure improvement is not certain and will be influenced by the following factors:

- The rate and location of regional development

- The location of development within the project site
- The type of development within the project site
- The implementation of roadway improvement constructed by others

Since the project is included in the County's 10-year CIP, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards this improvement.

Mitigation 9 - Cambridge Road/US 50 eastbound ramps (Intersection 12) – This intersection will be part of the planned Phase 1 improvements to the US 50/Cambridge Road Interchange, which are included in the County's 10-year CIP. Implementation of the following improvements to the Cambridge Road/US 50 eastbound ramps intersection would result in acceptable LOS B and C operation during the AM and PM peak hours, respectively:

- Install traffic signal control
- Provide one left-turn lane and a shared through lane on the northbound

Implementation of this improvement would result in acceptable LOS E or better operations during the AM and PM peak hours. With this improvement, this impact would be **less than significant**.

The analysis of the project under existing conditions assumes that the entire project develops immediately. However, development of the proposed project is anticipated to occur over 20 or more years. Consequently, the phasing of offsite infrastructure improvement is not certain and will be influenced by the following factors:

- The rate and location of regional development
- The location of development within the project site
- The type of development within the project site
- The implementation of roadway improvement constructed by others

Since the project is included in the County's 10-year CIP, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards this improvement.

Mitigation 10 - Cambridge Road/Flying C Road/Crazy Horse Road (Intersection 13) – Implementation of the following improvements to the Cambridge Road/Flying C Road/Crazy Horse

Road intersection would result in acceptable LOS C operation during the AM peak hour and LOS B operation during the PM peak hour:

- Install traffic signal control
- Provide one left-turn lane and a shared through/right-turn lane on the northbound and southbound approaches
- Provide protected left-turn phasing on the northbound and southbound approaches

Implementation of this improvement would result in acceptable LOS E or better operations during the AM and PM peak hours. With this improvement, this impact would be **less than significant**.

The analysis of the project under existing conditions assumes that the entire project develops immediately. However, development of the proposed project is anticipated to occur over 20 or more years. Consequently, the phasing of offsite infrastructure improvement is not certain and will be influenced by the following factors:

- The rate and location of regional development
- The location of development within the project site
- The type of development within the project site
- The implementation of roadway improvement constructed by others

If constructed by others prior to residential development levels in the project site that would require this mitigation, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards this improvement. If not constructed by others, the applicant would be responsible for implementing this improvement consistent with General Plan Goal TC-X and supporting Policy TC-Xf to ensure that transportation improvements are implemented concurrent with approved residential development. If constructed by the applicant, the applicant would be subject to fee credit or reimbursement through the County's traffic impact mitigation fee program.

Mitigation 11 - El Dorado Hills Boulevard/Park Drive/Saratoga Way (Intersection 19) – Implementation of the US 50/El Dorado Hills Boulevard interchange improvements, which are currently under construction, would result in acceptable LOS C operations at El Dorado Hills Boulevard/Park Drive/Saratoga Way intersection during the AM and PM peak hours. With this improvement, this impact would be **less than significant**.

This improvement will be completed prior to development in the project site.

Therefore, payment of traffic impact mitigation fees will satisfy the project's fair share obligation towards this improvement.

Mitigation 12 - Latrobe Road/Town Center Boulevard (Intersection 21) – Implementation of the US 50/El Dorado Hills Boulevard interchange improvements, which are currently under construction and the addition of a westbound right-turn overlap phase or opening the north leg of the White Rock Road/Town Center Drive intersection (full improvements are constructed), would result in acceptable LOS C and E operations at the Latrobe Road/Town Center Boulevard intersection during the AM and PM peak hours, respectively. Unacceptable operations at this intersection are due primarily to poor lane utilization on northbound Latrobe Road during construction. With this improvement, this impact would be **less than significant**.

The improvements at the US 50/El Dorado Hills Boulevard interchange will be completed prior to development in the project site. Therefore, payment of traffic impact mitigation fees will satisfy the project's fair share obligation towards this improvement. The project would be responsible for the cost to implement right-turn overlap phasing or opening the north leg of the White Rock Road/Town Center Drive intersection.

TABLE 16: INTERSECTION LOS AND DELAY – EXISTING PLUS PROJECT MITIGATIONS

Intersection	LOS Target	Control	Existing Conditions		Existing + Project Conditions		Existing + Project Mitigations	
			AM Peak Hour	PM Peak Hour	AM Peak Hour	PM Peak Hour	AM Peak Hour	PM Peak Hour
1. Bass Lake Road/Serrano Parkway	E	AWSC	D / 31	B / 13	<u>F / 61</u>	C / 18	B / 19	B / 11
4. Bass Lake Road/Country Club Drive	D	SSSC	F / >180	C / 22	<u>F / > 180</u>	<u>F / 129</u>	C / 23	B / 11

TABLE 16: INTERSECTION LOS AND DELAY – EXISTING PLUS PROJECT MITIGATIONS

Intersection	LOS Target	Control	Existing Conditions		Existing + Project Conditions		Existing + Project Mitigations	
			AM Peak Hour	PM Peak Hour	AM Peak Hour	PM Peak Hour	AM Peak Hour	PM Peak Hour
19. El Dorado Hills Boulevard/Park Drive/Saratoga Way	E	Signal	D / 36	C / 25	<i>F / 103</i>	C / 23	C / 21	C / 21
21. Latrobe Road/Town Center Drive	E	Signal	C / 29	E / 75	C / 28	<i>F / 165</i>	C / 27	E / 62

Notes: AWSC = all-way stop control, SSSC = side-street stop control

Bold text indicates LOS worse than established threshold. *Italic* and underlined text identifies a potential impact.

The average delay is measured in seconds per vehicle. For signalized and AWSC intersections, the delay shown is the average control delay for the overall intersection. For SSSC intersections, the LOS and control delay for the worst movement is shown. Intersections 1, 4-10, and 12-13 are analyzed in Synchro. Intersections 19 and 20 are analyzed in SimTraffic.

Intersection LOS and delay is calculated based on the procedures and methodology contained in the HCM (TRB, 2000).

7.1.2 FREEWAY FACILITIES

The addition of project traffic will impact US 50 operations under existing conditions. The analysis results are presented in Table 17.

Impacts

- Impact 13 - US 50/Westbound Bass Lake Road On-Ramp – The addition of project traffic will result in LOS F conditions at the US 50 westbound on-ramp from Bass Lake Road. **This is a significant impact.**
- Impact 14 - US 50/Westbound El Dorado Hills Boulevard Off-Ramp – The addition of project traffic will result in LOS F conditions at the US 50 westbound off-ramp to El Dorado Hills Boulevard. **This is a significant impact.**
- Impact 15 - US 50/Westbound El Dorado Hills Boulevard On-Ramp – The addition of project traffic will result in LOS F conditions at the US 50 westbound on-ramp from El Dorado Hills Boulevard. **This is a significant impact.**

Mitigation

- Mitigation 13 - US 50/Westbound Bass Lake Road On-Ramp – Implementation of the first phase of the US 50/Bass Lake Road interchange improvements, which are in the County's 10-year CIP, would result in acceptable LOS D (or better) and LOS B operations at westbound on-ramp merge area during the AM and PM peak hours, respectively. With this improvement, this impact would be **less than significant**.

Implementation of this improvement would result in acceptable LOS D or better operations during the AM and PM peak hours. With this improvement, this impact would be **less than significant**.

Since the project is included in the County's 10-year CIP, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards this improvement.

- Mitigation 14 - US 50/Westbound El Dorado Hills Boulevard Off-Ramp – Implementation of the US 50/Silva Valley Parkway interchange improvements, which is currently under construction, would result in acceptable LOS D and LOS B operations at westbound on-ramp merge area during the AM and PM peak hours, respectively. With this improvement, this impact would be **less than significant**.

Implementation of this improvement would result in acceptable LOS E or better operations during the AM and PM peak hours. With this improvement, this impact would be **less than significant**.

The analysis of the project under existing conditions assumes that the entire project develops immediately. However, development of the proposed project is anticipated to occur over 20 or more years. Consequently, the phasing of offsite infrastructure improvement is not certain and will be influenced by the following factors:

- The rate and location of regional development
- The location of development within the project site
- The type of development within the project site
- The implementation of roadway improvement constructed by others

Since the improvements are either under construction or included in the County's 10-year CIP, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards the improvements.

Mitigation 15 - US 50/Westbound El Dorado Hills Boulevard On-Ramp – Implementation of the US 50/El Dorado Hills Boulevard interchange and US 50/Silva Valley Parkway interchange improvements, which are currently under construction, and the two-lane extension of Saratoga Way (Finders Way to Iron Point Road in the City of Folsom), which is in the County's 10-year CIP, would result in acceptable LOS D operations at westbound on-ramp merge area during the AM and PM peak hours:

With these improvements, this impact would be **less than significant**.

Since the improvements are either under construction or included in the County's 10-year CIP, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards these improvements.

**TABLE 17: FREEWAY FACILITY PEAK HOUR LEVEL OF SERVICE – EXISTING PLUS PROJECT CONDITIONS
MITIGATION**

Freeway	Segment	Facility Type	Existing Density ¹ / LOS		Existing + Project Density ¹ / LOS		Existing + Project Mitigation Density ¹ / LOS	
			AM	PM	AM	PM	AM	PM
US 50 WB	Bass Lake Rd on-ramp	Merge ²	31 / D	20 / C	<u>- / F</u>	26 / C	31 / D	21 / C
							23 / C	14 / B
	El Dorado Hills Blvd off-ramp	Diverge/Leisch ³	33 / D	22 / C	<u>- / F</u>	28 / D	- / D	16 / B
	El Dorado Hills Blvd on-ramp	Merge	34 / D	24 / C	<u>- / F</u>	28 / D	26 / C	21 / C

Notes: ¹Density reported as passenger cars per mile per lane. Density is not reported for LOS F operations. Analysis based on HCM 2010. Weave segment's operations are based on the HCM 2010 and Leisch Method. If the weave segment is outside the realm of weaving, it is analyzed as a basic segment.

²Mitigation scenario reflects interchange improvements that includes a loop and slip on-ramp

³Mitigation scenario includes Silva Valley interchange, therefore is analyzed as a weave segment using the Leisch Method or a basic segment.

Bold text indicates LOS worse than established threshold. *Italic and underlined* text identifies a potential impact.

7.2 CUMULATIVE PLUS PROJECT

Analysis results, which are presented in Table 18, indicate that the addition of the project would exacerbate unacceptable operations at 12 study intersections and result in unacceptable operations at two intersections. The following discusses these impacts and associated mitigation:

7.2.1 INTERSECTIONS

Impacts

- Impact 16 - Bass Lake Road/Serrano Parkway (Intersection 1) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours. **This is a significant impact.**

- Impact 17 - Bass Lake Road/Hollow Oak Drive (Intersection 2) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours. **This is a significant impact.**
- Impact 18 - Bass Lake Road/Old Bass Lake Road (Intersection 3) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours. **This is a significant impact.**
- Impact 19 - Bass Lake Road/Country Club Drive (Intersection 4) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours. **This is a significant impact.**
- Impact 20 - Bass Lake Road/US 50 westbound ramps (Intersection 5) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection will operate unacceptably at LOS E in the AM peak hour and LOS F in the PM peak hour without the project. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours. Poor operation at this intersection will result in vehicle queuing on the westbound off ramp during the PM peak hour that could cause vehicles to spill back to the US 50 mainline, impacting mainline operations. **This is a significant impact.**
- Impact 21 - Bass Lake Road/US 50 eastbound ramps (Intersection 6) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection will operate unacceptably at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours. Poor operation at this intersection will result in vehicle queuing on the eastbound off ramp during the PM peak hour that could cause vehicles to spill back to the US 50 mainline, impacting mainline operations. **This is a significant impact.**
- Impact 22 - Marble Valley Parkway/Marble Mountain Road (Intersection 7) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection will operate acceptably at LOS D without the project

during the AM and PM peak hours. The project results in unacceptable (LOS F) conditions during the AM and PM peak hours. **This is a significant impact.**

- Impact 23 - Marble Valley Parkway/Marble Ridge Road (Intersection 8) – This intersection is located in the County’s Rural Region and is subject to the LOS D significance threshold. This intersection will operate acceptably at LOS C during the AM peak hour and unacceptably at LOS E without the project during the PM peak hour. The project will also result in unacceptable (LOS F) conditions during the AM peak hour and according to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the PM peak hour. **This is a significant impact.**
- Impact 24 - Cambridge Road/Country Club Drive (Intersection 9) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours. **This is a significant impact.**
- Impact 25 - Cambridge Road/Knollwood Drive (Intersection 10) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours. **This is a significant impact.**
- Impact 26 - Cambridge Road/US 50 westbound ramps (Intersection 11) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours. **This is a significant impact.**
- Impact 27 - Cambridge Road/Flying C Road/Crazy Horse Road (Intersection 13) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours. **This is a significant impact.**
- Impact 28 - El Dorado Hills Boulevard/Park Drive/Saratoga Way (Intersection 19) – This intersection will operate acceptably at LOS D during the AM peak hour and unacceptably at LOS F without the project during the PM peak hour. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the PM peak hour. **This is a significant impact.**

Impact 29 - Latrobe Road/Town Center Drive (Intersection 21) – This intersection will operate at LOS F without the project during the AM and PM peak hours. According to established significance criteria, the project is projected to “significantly worsen” conditions, since it would add more than 10 trips to the intersection during the AM and PM peak hours. **This is a significant impact.**

Mitigation

Mitigation 16 - A traffic signal has been constructed at the Bass Lake Road/Serrano Parkway intersection as part of the realignment of Sienna Ridge Road. Traffic signal control will result in acceptable LOS B and LOS C operation during the AM and PM peak hours, respectively. With this improvement, this impact would be **less than significant**.

Mitigation 17 - Bass Lake Road/Hollow Oak Drive (Intersection 2) – Implementation of the following improvements to the Bass Lake Road/Hollow Oak Drive intersection would result in acceptable LOS B operation during the AM and PM peak hours:

- Install traffic signal control

Implementation of this improvement would result in acceptable LOS E or better operations during the AM and PM peak hours. With this improvement, this impact would be **less than significant**.

The widening of Bass Lake Road from two to four lanes from US 50 to Silver Springs Parkway is in the County’s CIP. As a funded project, the widening of this segment was assumed in the cumulative conditions analysis. This signalization of the Bass Lake Road/Hollow Oak Drive intersection would likely be part of the planned widening of Bass Lake Road. Payment of traffic impact mitigation fees would satisfy the project’s fair share obligation towards this improvement.

Mitigation 18 - Bass Lake Road/Old Bass Lake Road (Intersection 3) – Implementation of the following improvements to the Bass Lake Road/Old Bass Lake Road intersection would result in acceptable LOS B and A operations during the AM and PM peak hours, respectively:

- Install traffic signal control

With this improvement, this impact would be **less than significant**.

The widening of Bass Lake Road from two to four lanes from US 50 to Silver Springs Parkway is in the County’s CIP. As a funded project, the widening of this segment was assumed in the cumulative conditions analysis. This signalization of the Bass Lake Road/Old Bass Lake Road intersection would likely be part of the planned widening of Bass Lake Road. Payment of traffic impact mitigation fees would satisfy the project’s fair share obligation towards this improvement.

Mitigation 19 - Bass Lake Road/Country Club Drive (Intersection 4) – This intersection will be part of the planned widening of Bass Lake Road and the reconstruction of the US 50/Bass Lake Road interchange, which are included in the County's 10-year CIP. Implementation of the US 50/Bass Lake Road interchange reconstruction project, which has not been designed, would result in acceptable LOS D operation during the AM and PM peak hours at the Bass Lake Road/Country Club Drive intersection. The following improvements would provide acceptable operation:

- Relocate Country Club Drive north of its current intersection with Bass Lake Road to improve intersection spacing with the interchange ramp intersections.
- Reconstruct US 50/Bass Lake Road interchange to provide a Type L-9 Configuration, which includes slip on- and off-ramps, southbound-to-eastbound and northbound-to-westbound loop on-ramps, and a four- to five-lane overcrossing.
- Provide traffic signal control at the Bass Lake Road/Country Club Drive (Intersection 4), Bass Lake Road/US 50 westbound ramps (Intersection 5) intersection and at the Bass Lake Road/US 50 eastbound ramps (Intersection 6) with coordinated traffic signal operation.
- Construct the Marble Valley Parkway connection (i.e., the two-lane connection that lies outside the project area) that will complete Marble Valley Parkway between Marble Lake Boulevard and Cambridge Road.

The project identified in the CIP describes reconstruction of the interchange at its current location, which would be a similar to the US 50/EI Dorado Hills Boulevard interchange. An alternative approach, that should be considered, would relocate the interchange east of its current location, similar to the US 50/Silva Valley Parkway interchange. This approach would provide for a more flexible design, implementation phasing, and allow use of the current US 50 undercrossing for local access.

Implementation of this improvement would result in acceptable LOS D or better operations during the AM and PM peak hours. With this improvement, this impact would be **less than significant**.

Since the project is included in the County's 10-year CIP, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards this improvement.

Mitigation 20 - Bass Lake Road/US 50 westbound ramps (Intersection 5) – This intersection will be part of the planned reconstruction of the US 50/Bass Lake Road interchange, which is included in the County's CIP. Implementation of Mitigation 17 would provide LOS C operation in the AM and PM peak hour. With this improvement, this impact would be **less than significant**.

Mitigation 21 - Bass Lake Road/US 50 eastbound ramps (Intersection 6) – This intersection will be part of the planned reconstruction of the US 50/Bass Lake Road interchange, which is included in the County's CIP. Implementation of Mitigation 17 would provide LOS B and C operation in the AM and PM peak hours, respectively. With this improvement, this impact would be **less than significant**.

Mitigation 22 - Marble Valley Parkway/Marble Mountain Road (Intersection 7) – This intersection will be part of the planned reconstruction of the US 50/Bass Lake Road interchange, which is included in the County's CIP. Implementation of Mitigation 17 would provide LOS A operation in the AM and PM peak hour. With this improvement, this impact would be **less than significant**.

Mitigation 23 - Marble Valley Parkway/Marble Ridge Road (Intersection 8) – This intersection will be part of the planned reconstruction of the US 50/Bass Lake Road interchange, which is included in the County's CIP. Implementation of Mitigation 17 would provide LOS A operation in the AM and PM peak hour. With this improvement, this impact would be **less than significant**.

Mitigation 24 - Cambridge Road/Country Club Drive (Intersection 9) – Implementation of the following improvements to the Cambridge Road/Country Club Drive intersection would result in acceptable LOS D operation during the AM and PM peak hours, respectively:

- Install traffic signal control
- Provide one left-turn lane and a shared through/right-turn lane on the northbound and southbound approaches
- Provide protected left-turn phasing on the northbound and southbound approaches

Implementation of this improvement would result in acceptable LOS E or better operations during the AM and PM peak hours. With this improvement, this impact would be **less than significant**.

The Cumulative analysis includes planned and funded roadway improvements, growth consistent with the 2004 General Plan, and with approved and reasonably foreseeable projects within the study area. This is found to be an impact in the cumulative scenario without the project, but with other unapproved projects. The project

proponent shall work with the County, during the development agreement phase, or development of the public financing plan or like process, to evaluate and determine the appropriate mitigation measures. Appropriate mitigation measures can include construction of project, fair share payments, etc.

Mitigation 25 - Cambridge Road/Knollwood Drive (Intersection 10) – This intersection will be part of the planned Phase 1 improvements to the US 50/Cambridge Road Interchange, which are included in the County's 10-year CIP. This intersection will be part of the reconstruction of the US 50/Cambridge Road interchange, which is included in the County's CIP. Implementation of the US 50/Cambridge Road interchange reconstruction project, which has not been designed, would result in acceptable LOS E operation during the AM and PM peak hours at the Cambridge Road/Knollwood Drive intersection. The following improvements would provide acceptable operation:

- Reconstruct the US 50/Cambridge Road interchange with a four-lane overcrossing
- Install traffic signal control
- Provide two left-turn lanes, one through lane, and a right-turn lane on the northbound approach
- Provide one left-turn lane and a shared through/right-turn lane on the southbound approach
- Provide a shared through/left-turn lane and separate right-turn lane on the eastbound approach with right-turn overlap phasing
- Provide a separate left-turn lane and a shared left/through/right-turn lane on the westbound approach
- Provide split phasing eastbound and westbound

The reconstruction of the US 50/Cambridge Road interchange is in the County's CIP. Caltrans project programming and corresponding design of this interchange has not been conducted. Due to its close spacing to the US 50/Cambridge Road interchange westbound ramp-terminal intersection, improvement to the Cambridge Road/Knollwood Drive intersection would likely be part of the interchange reconstruction project.

Since the project is included in the County's 10-year CIP, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards this improvement.

Mitigation 26 - Cambridge Road/Merrychase Drive/US 50 westbound ramps (Intersection 11) – This intersection will be part of the planned Phase 1 improvements to the US 50/Cambridge Road Interchange, which are included in the County's 10-year CIP.

Implementation of the following improvements to the Cambridge Road/Merrychase Drive/US 50 westbound ramps intersection would result in acceptable LOS E operation during the AM and PM peak hours:

- Reconstruct the US 50/Cambridge Road interchange with a four lane overcrossing
- Install traffic signal control
- Provide one left-turn lane, two through lanes, and a right-turn lane (to the loop on-ramp) on the northbound approach
- Provide one left-turn lane, one through lane, and a shared through/right-turn lane on the southbound approach
- Provide a shared through/left-turn lane and a right-turn lane on the eastbound approach
- Provide two left-turn lanes, a shared through/right-turn lane, and a separate right-turn lane on the westbound approach

The reconstruction of the US 50/Cambridge Road interchange is in the County's CIP. Caltrans project programming and corresponding design of this interchange has not been conducted.

Since the project is included in the County's 10-year CIP, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards this improvement.

Mitigation 27 - Cambridge Road/Flying C Road/Crazy Horse Road (Intersection 13) – Implementation of the following improvements to the Cambridge Road/Flying C Road/Crazy Horse Road intersection would result in acceptable LOS C and D operation during the AM and PM peak hours, respectively:

- Reconstruct the US 50/Cambridge Road interchange with a four lane overcrossing
- Install traffic signal control
- Provide one left-turn lane, one through lane, and a shared through/right-turn lane on the northbound approach
- Provide one left-turn lane, one through lane, and a right-turn lane on the southbound approach
- Provide a shared left/through/right-turn lane on the eastbound and westbound approach

The reconstruction of the US 50/Cambridge Road interchange is in the County's CIP. Caltrans project programming and corresponding design of this interchange has not been conducted. Due to its close spacing to the US 50/Cambridge Road interchange eastbound ramp-terminal intersection, improvement to the Cambridge Road/Flying C Road/Crazy Horse Road intersection would likely be part of the interchange reconstruction project.

If constructed by others prior to residential development levels in the project site that would require this mitigation, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards this improvement. If not constructed by others, the applicant would be responsible for implementing this improvement consistent with General Plan Goal TC-X and supporting Policy TC-Xf to ensure that transportation improvements are implemented concurrent with approved residential development. If constructed by the applicant, the applicant would be subject to fee credit or reimbursement through the County's traffic impact mitigation fee program.

Mitigation 28 - El Dorado Hills Boulevard/Park Drive/Saratoga Way (Intersection 19) – Implementation of the following improvements to the El Dorado Hills Boulevard/Park Drive/Saratoga Way intersection would result in acceptable LOS D operations during the PM peak hour:

- Modify the northbound approach to provide one left-turn lane, three through lanes, and a separate right-turn lane
- Modify the eastbound approach to provide two left-turn lanes, one through lane, and a separate right-turn lane
- Modify the westbound approach to provide one left-turn lane, one through lane, and a separate right-turn lane
- Provide protected left-turn phasing east and westbound
- Optimize traffic signal timings to accommodate the revised intersection lane configurations
- Restrict access at the Saratoga Way/Mammoth Way intersection to right-in/right-out
- Install a traffic signal at the Saratoga Way/Arrowhead Drive intersection

With this improvement, this impact would be **less than significant**.

Elements of these improvements are either under construction or included in the County's 10-year CIP. The 10-year CIP includes widening of El Dorado Hills Boulevard

as part of the US 50 interchange improvements and as a separate project between Saratoga Way/Park Drive and Serrano Parkway/Lassen Lane that will add a third southbound through lane. In addition, the Saratoga Way extension (as a four-lane roadway) to Iron Point Road in the City of Folsom will improve the eastbound approach to this intersection.

Improvements to the west leg of the intersection (i.e., Saratoga Way) are needed to accommodate traffic volume increases associated primarily with the extension of Saratoga Way to Iron Point Road and not directly a result of the proposed project. The Saratoga Way Extension project will increase southbound-to-westbound traffic demand in the AM peak hour and traffic demand for the reverse movement (eastbound-to-northbound) in the PM peak hour. Consequently, most of improvements to Saratoga Way (i.e., the west leg) will not be necessary until the Saratoga Way Extension is constructed, except restriping to accommodate protected east/west left-turn phasing. However, improvements to Park Drive (i.e., east leg of the intersection) are needed to accommodate traffic from the proposed project.

Since the project is included in the County's 10-year CIP, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards this improvement.

Mitigation 29 - Latrobe Road/Town Center Boulevard (Intersection 21) – Implementation of the following improvements to the Latrobe Road/Town Center Boulevard intersection would result in acceptable LOS D and E operations during the AM and PM peak hours, respectively:

- Modify the northbound approach to provide two left-turn lanes, three through lanes, and a shared through/ right-turn lane
- Modify the westbound approach to provide a shared through/left-turn lane, and two right-turn lanes
- Provide right-turn overlap phasing for the westbound approach
- Provide split phasing east and westbound
- Optimize traffic signal timings to accommodate the revised intersection lane configurations

With this improvement, this impact would be **less than significant**.

The widening of El Dorado Hills Boulevard is currently under construction as part of the US 50 interchange improvements. These planned improvements will accommodate the intersection lane configurations outlined above. Payment of traffic impact mitigation fees will satisfy the project's fair share obligation towards improvements at this intersection.

TABLE 18: INTERSECTION LOS AND DELAY – CUMULATIVE PLUS PROJECT MITIGATIONS

Intersection	LOS Target	Control	Cumulative Conditions		Cumulative + Project Conditions		Project Mitigations
			AM Peak Hour	PM Peak Hour	AM Peak Hour	PM Peak Hour	

1. Bass Lake Road/Serrano Parkway	E	AWSC	F / 112	F / 84	F / 69	F / 70	B / 15	C / 25
2. Bass Lake Road/Hollow Oak Drive	E	SSSC	F / < 180	F / < 120	F / < 180	F / < 180	B / 14	B / 14
3. Bass Lake Road/Old Bass Lake Road	D	SSSC	F / < 180	F / < 180	F / < 180	F / < 180	B / 19	A / 10
4. Bass Lake Road/Country Club Drive	D	SSSC	F / < 180	F / < 180	F / < 180	F / < 180	D / 47	D / 53

21. Latrobe Rd/Town Center Dr	E	Signal	F / 87	F / 152	<u>F / 86</u>	<u>F / 166</u>	D / 47	E / 75

Note: SSSC = side-street stop control, AWSC = all-way stop control

Bold text indicates LOS worse than established threshold. *Italic and underlined* text identifies a potential impact.

The average delay is measured in seconds per vehicle. For signalized and AWSC intersections, the delay shown is the average control delay for the overall intersection. Intersections 1-6, 9-11, and 13 are analyzed in Synchro 7. Intersections 19 and 21 are analyzed in SimTraffic.

Source: Fehr & Peers, 2014

7.2.2 ROADWAYS

Analysis results, which are presented in Table 19, indicate that the addition of the project would significantly worsen unacceptable operations on one study roadway segment. The following discusses this impact and associated mitigation:

- Impact 30 - Cameron Park Drive (Alhambra Drive and Oxford Road) – This roadway segment would operate unacceptably at LOS F without the project during the PM peak hour. According to established significance criteria, the project is projected to “significantly

worsen” conditions, since it would add more than 10 trips to the roadway segment during the PM peak hours. **This is a significant impact.**

Mitigation 30 - Cameron Park Drive (Alhambra Drive and Oxford Road) – Implementation of the following improvements to this segment of Cameron Park Drive would result in acceptable LOS D or better operations during the AM and PM peak hours:

- Widen the segment of Cameron Park Drive from a two-lane arterial to a four-lane (undivided or divided) arterial.

Unacceptable operations on this roadway segment are due to increased traffic from planned development. This improvement is not in the County’s CIP. Since the roadway segment would operate unacceptably at LOS F under cumulative conditions without the project, the project is responsible for a portion of the improvement to restore operations to an acceptable level of service, relative to the traffic that the project will contribute to the roadway under cumulative conditions.

The County’s traffic impact mitigation fee program provides a mechanism for collecting fair share contributions for improvements in the CIP. The CIP is evaluated annually in response to planned growth. This improvement is not in the current CIP. Since this improvement is needed to accommodate planned growth, this improvement should be incorporated into the CIP at a future date as necessary to provide acceptable operations, consistent with General Plan Policy TC-Xf. Payment of traffic impact mitigation fees will satisfy the project’s fair share obligation towards this improvement.

TABLE 19: ROADWAY SEGMENT PEAK HOUR LEVEL OF SERVICE – CUMULATIVE PLUS PROJECT CONDITIONS MITIGATIONS

Roadway	Segment	Facility Type	Cumulative Volume / Volume – Capacity (V/C) Ratio / LOS		Cumulative + Project Volume / Volume – Capacity (V/C) Ratio / LOS		Cumulative + Project Mitigation Volume / Volume – Capacity (V/C) Ratio / LOS	
			AM Peak Hour	PM Peak Hour	AM Peak Hour	PM Peak Hour	AM Peak Hour	PM Peak Hour
Cameron Park Drive	Alhambra Drive to Oxford Road	2 lane arterial	1,500 / 0.91 / D	1,750 / 1.06 / F	1,510 / 0.92 / D	<u>1,770 / 1.07 / F</u>		
		4 lane arterial (Undivided)					1,510 / 0.48 / C	1,770 / 0.57 / D
		2 lane arterial (Divided)					1,510 / 0.46 / C	1,770 / 0.54 / C

Notes: ¹LOS at this location is C or better
Volume-to-Capacity ratio and LOS is based on the HCM 2010 peak hour level of service thresholds
Bold text indicates LOS worse than established threshold. *Italic and underlined* text identifies a potential impact.
Source: Fehr & Peers, 2014

7.2.3 FREEWAY FACILITIES

Analysis results, which are presented in Table 20, indicate that the addition of the project would result in unacceptable operations on one study freeway facility. The following discusses this impact and associated mitigation:

Impact 31 - US 50 Westbound Weave Section (El Dorado Hills Boulevard to Empire Ranch Road) – The addition of project traffic will result in LOS F conditions at the US 50 westbound weave section between El Dorado Hills Boulevard and Empire Ranch Road. **This is a significant impact.**

Mitigation 31 - US 50 Westbound Weave Section (El Dorado Hills Boulevard to Empire Ranch Road) – Implement the Latrobe Road Connection (CIP Project Number 66166) as a four-lane roadway would result in LOS E and D operation in the AM and PM peak hours, respectively. With this improvement, this impact would be **less than significant**.

The connection will improve accessibility for planned development south of US 50 and provide an alternative to the US 50/El Dorado Hills Boulevard Interchange and US 50 between El Dorado Hills Boulevard and Empire Ranch Road.

Development of the proposed project is anticipated to occur over 20 or more years. Consequently, the phasing of offsite infrastructure improvement is not certain and will be influenced by the following factors:

- The rate and location of regional development
- The location of development within the project site
- The type of development within the project site
- The implementation of roadway improvement constructed by others

If constructed by others prior to residential development levels in the project site that would require this mitigation, payment of traffic impact mitigation fees would satisfy the project's fair share obligation towards this improvement. If not constructed by others, the applicant would be responsible for implementing this improvement consistent with General Plan Goal TC-X and supporting Policy TC-Xf to ensure that transportation improvements are implemented concurrent with approved residential development. If constructed by the applicant, the applicant would be subject to fee credit or reimbursement through the County's traffic impact mitigation fee program.

TABLE 20: FREEWAY FACILITY PEAK HOUR LEVEL OF SERVICE – CUMULATIVE PLUS PROJECT CONDITIONS MITIGATION

Freeway	Segment	Facility Type	Cumulative Density ¹ / LOS		Cumulative + Project Density ¹ / LOS		Cumulative + Project Mitigation Density ¹ / LOS	
			AM	PM	AM	PM	AM	PM
US 50 WB	El Dorado Hills Blvd to Empire Ranch Rd	Weave	44 / E	34 / D	<u>-/F</u>	34 / D	43 / E	33 / D

TABLE 20: FREEWAY FACILITY PEAK HOUR LEVEL OF SERVICE – CUMULATIVE PLUS PROJECT CONDITIONS MITIGATION

Freeway	Segment	Facility Type	Cumulative Density ¹ / LOS		Cumulative + Project Density ¹ / LOS		Cumulative + Project Mitigation Density ¹ / LOS	
			AM	PM	AM	PM	AM	PM

Notes: ¹Density reported as passenger cars per mile per lane. Density is not reported for LOS F operations. Analysis based on HCM 2010. Weave segment's operations are based on the HCM 2010 and Leisch Method. If the weave segment is outside the realm of weaving, it is analyzed as a basic segment.

Bold text indicates LOS worse than established threshold. *Italic and underlined* text identifies a potential impact.

Source: Fehr & Peers, 2014

7.2.4 PEDESTRIAN AND BICYCLE FACILITIES

Impact 32 - Implementation of the proposed project will increase demand for pedestrian and bicycle facilities. As outlined in Section 6.3, the project proposes pedestrian and bicycle facilities that will connect and integrate with existing and planned facilities adjacent to the project. In addition, elements of the proposed project will provide new recreational opportunities. Therefore, the proposed project will not conflict with adopted policies, plans, or programs regarding bicycle, or pedestrian facilities, or otherwise decrease the performance or safety of such facilities. **This is a less than significant impact.**

Mitigation 32 - No mitigation required

7.2.5 TRANSIT

Impact 33 - Implementation of the proposed project will increase demand transit. As outlined in Section 6.4, the project could result in demand of about 8,400 transit commute trips annually, which would be an average of about 32 commute trips per weekday. This increase represents about a 20 percent increase in El Dorado Transit Commuter Service. The growth in commute trips would not likely exceed the ability to serve this ridership growth through existing funding sources for transit that are tied to population growth. However, most of the boardings for the El Dorado Transit Commuter Service at the El Dorado Hills park-n-ride lot are from El Dorado Hills residents. Consequently this increase in commuter trips will increase demand for the El Dorado Hills and Cameron Park park-n-ride lot, which operate at or near capacity. **This is a significant impact.**

Mitigation 33 - The project will provide a 100 to 120 space park-n-ride lot, which would accommodate the estimated demand for park-n-ride facilities anticipated by the project. Therefore, Implementation of the project, which includes park-n-ride facilities would reduce this impact to a **less than significant level**.

7.2.6 EMERGENCY ACCESS

Impact 34 - The proposed project will provide two points of access from the US 50/Bass Lake Road and US 50/Cambridge Road interchanges and an emergency vehicle access to the west towards the Valley View and East Ridge Specific Plan areas for emergency vehicle access. This is a **less than significant impact**.

Mitigation 34 - No mitigation required

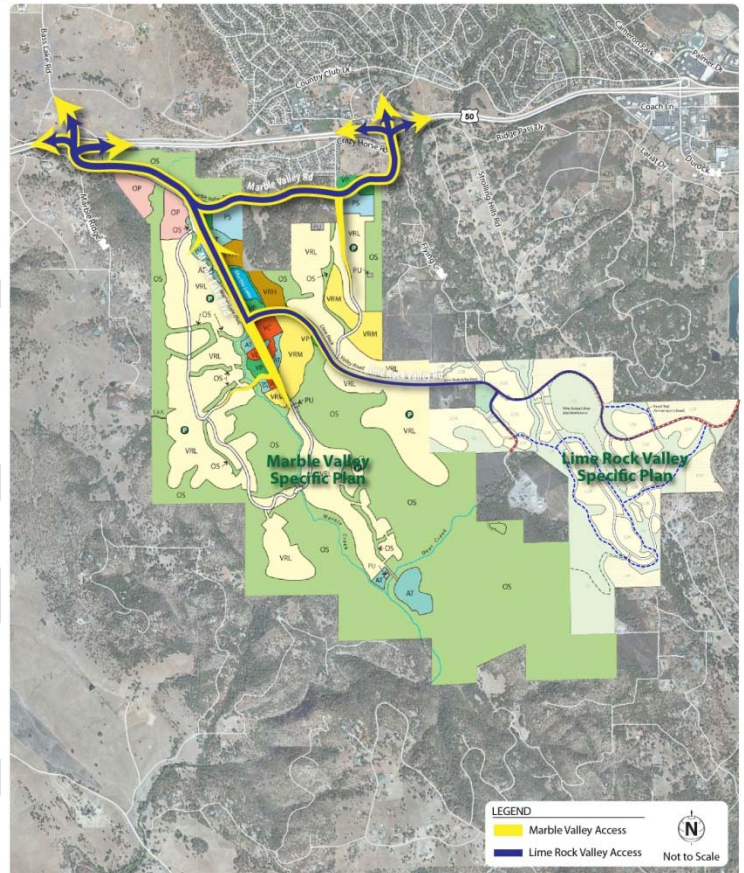

8.0 OTHER CONSIDERATIONS

8.1.1 SITE ACCESS

Proposed circulation for the Village of Marble Valley Specific Plan is shown to the right. US 50 access will be through the US 50/Bass Lake Road and US 50/Cambridge Road interchanges. Marble Valley Parkway is proposed as a continuous roadway connecting the Bass Lake Road and Cambridge Road interchanges. A portion of Marble Valley Parkway is outside the plan area. Marble Lake Boulevard, which is planned as a four- to two-lane roadway, will provide be the primary access roadway with major internal intersections along are planned as roundabouts. Lime Rock Valley Boulevard will extend east of Marble Lake Boulevard as a two-lane roadway.

Figure 13 shows the proposed intersection layout and lane assumptions for Marble Lake Boulevard necessary to support the Village of Marble Valley and the proposed Lime Rock Valley Specific Plan, which is located just east of the proposed project given the planned access discussed above. The following summarizes the key design features of the proposed intersections:

- Intersection 1 - A two-lane roundabout with a northbound-to-eastbound right-turn bypass lane.
- Intersection 2 - A two-lane roundabout with a southbound-to-westbound right-turn bypass lane.
- Intersection 3 - A couplet intersection with one northbound and one southbound lane on Marble Lake Boulevard (uncontrolled) and stop controls at all of the minor movements (eastbound and westbound).
- Intersection 4 - A two-lane roundabout with a westbound-to-northbound right-turn bypass lane.
- Intersection 5 - A single lane roundabout.

Marble Lake Boulevard would be four lanes from US 50 to just south of Intersection 2. As shown in Table 21, the study intersections would operate acceptably with the proposed lane configurations. Detailed input assumptions and analysis results are included in Appendix A.

DRAFT

Figure 13: Marble Lake Boulevard Concept **[Revised Figures Pending]**

DRAFT

TABLE 22: PEAK HOUR SIGNAL WARRANT EVALUATION – EXISTING PLUS PROJECT CONDITIONS

An evaluation of the need for traffic signal installation was conducted using the peak hour traffic signal warrant methodologies from the California Manual on Uniform Traffic Control Devices, January 2012. Tables 22 and 23 display the results of the peak hour volume warrant for existing and cumulative conditions, respectively. Under existing conditions, all of the intersections evaluated would satisfy the peak hour signal warrant during at least one peak hour except for the Cambridge Road/Country Club Drive intersection. Under cumulative conditions, all intersections evaluated would satisfy the peak hour volume warrant.

8.1.2 PEAK HOUR TRAFFIC SIGNAL WARRANT EVALUATION

Notes: SSSC = side-street stop-control, AWSC = all-way stop control. The average delay is measured in seconds per vehicle. For signalized and AWSC intersections, the delay shown is the average control delay for the overall intersection. For Roundabout and SSSC intersections, the LOS and control delay for the worst movement is shown. Intersection LOS and delay is calculated based on the procedures and methodology contained in the HCM (TRB, 2000). Intersections 1-14, and 17-18 are analyzed in Synchro 7. Intersections 15-16 are analyzed in SimTraffic. Source: Fehr & Peers, 2014

Intersection	LOS Target	Traffic Control	LOS / Delay (seconds)	
			AM Peak Hour	PM Peak Hour
1. Marble Lake Boulevard (Intersection 1)	D	Roundabout	C / 17	D / 27
2. Marble Lake Boulevard (Intersection 2)	D	Roundabout	D / 32	B / D
3. Marble Lake Boulevard (Intersection 3)	D	SSSC	D / 34	D / 30
4. Marble Lake Boulevard/Lime Rock Valley Road (Intersection 4)	D	Roundabout	C / 22	B / 13
5. Marble Lake Boulevard (Intersection 5)	D	Roundabout	A / 9	A / 9

TABLE 21: PEAK HOUR LEVEL OF SERVICE – CUMULATIVE CONDITIONS (ON-SITE INTERSECTIONS)

	Existing Conditions		Existing + Project Conditions	
	AM	PM	AM	PM
1. Bass Lake Road / Serrano Parkway	No	No	Yes	Yes
4. Bass Lake Road / Country Club Drive	Yes	No	Yes	Yes
5. Bass Lake Road / US 50 WB Ramps	No	No	Yes	Yes
6. Bass Lake Road / US 50 EB Ramps	No	No	Yes	Yes
9. Cambridge Road / Country Club Drive	No	No	No	No
10. Cambridge Road / Knollwood Drive	No	No	Yes	No
12. Cambridge Road / US 50 EB Ramps	No	Yes	Yes	Yes

Notes: ¹Based on the Peak Hour Volume warrant (for urban areas) contained in the *California Manual on Uniform Traffic Control Devices* (CA MUTCD), Caltrans, 2012.

Source: Fehr & Peers, 2014

TABLE 23: PEAK HOUR SIGNAL WARRANT EVALUATION – CUMULATIVE CONDITIONS

Unsignalized Intersections	Peak Hour Signal Warrant Met ¹			
	Cumulative Conditions		Cumulative + Project Conditions	
	AM	PM	AM	PM
1. Bass Lake Road / Serrano Parkway	Yes	Yes	Yes	Yes
2. Bass Lake Road / Hollow Oak Drive	Yes	Yes	Yes	Yes
4. Bass Lake Road / Country Club Drive	Yes	Yes	Yes	Yes
5. Bass Lake Road / US 50 WB Ramps	Signalized intersection under cumulative conditions			
6. Bass Lake Road / US 50 EB Ramps	Signalized intersection under cumulative conditions			
9. Cambridge Road / Country Club Drive	No	Yes	No	Yes
10. Cambridge Road / Knollwood Drive	Yes	Yes	Yes	Yes
12. Cambridge Road / US 50 EB Ramps	Signalized intersection under cumulative conditions			

Note: ¹Based on the Peak Hour Volume warrant (for urban areas) contained in the *California Manual on Uniform Traffic Control Devices* (CA MUTCD), Caltrans, 2012.

Source: Fehr & Peers, 2014

This analysis is intended to examine the general correlation between the planned level of future development and the need to install new traffic signals. It estimates future development-generated traffic compared against a sub-set of the standard traffic signal warrants recommended in the Federal Highway Administration Manual on Uniform Traffic Control Devices (California MUTCD 2012 Edition). This analysis should not serve as the only basis for deciding whether and when to install a signal. To reach such a decision, the full set of warrants should be investigated based on field-measured, rather than forecast, traffic data and a thorough study of traffic and roadway conditions by an experienced engineer. Furthermore, the decision to install a signal should not be based solely upon the warrants, since the installation of signals can lead to certain types of collisions. El Dorado County should undertake regular monitoring of actual traffic conditions and accident data, and timely re-evaluation of the full set of warrants in order to prioritize and program intersections for signalization.

TECHNICAL MEMORANDUM

Date: March 8, 2021

To: Kirk Bone – Serrano Associates

From: David B. Robinson – Fehr & Peers

Subject: Village of Marble Valley Specific Plan VMT Analysis

RS12-3016

This memorandum presents vehicle miles traveled (VMT) analysis of the proposed Village of Marble Valley Specific Plan (VMVSP).

With the implementation of Senate Bill (SB) 743, local agencies such as El Dorado County may no longer rely on vehicular delay or capacity-based analyses for California Environmental Quality Act (CEQA) impact determination. Instead, agencies must analyze transportation impacts utilizing VMT, a measure of the total distance traveled by vehicles for trips beginning or ending in the County on a typical weekday. This memorandum covers the following topics:

- SB 743
- VMT Thresholds of Significance
- VMT Estimation Methodology
- Project Summary
- VMT for Village of Marble Valley Specific Plan

SB 743

Passed in 2013, SB 743 changes the focus of transportation impact analysis in CEQA from measuring impacts to drivers, to measuring the impact of driving. The change is being made by replacing LOS with vehicle miles of travel (VMT). This shift in transportation impact focus is intended to better align transportation impact analysis and mitigation outcomes with the State's goals to reduce greenhouse gas (GHG) emissions, encourage infill development, and improve public health through more active transportation. Level of service or other delay metrics may still be used to evaluate the impact of projects on drivers as part of land use entitlement review and impact fee programs.

In January 2019, the Natural Resources Agency finalized updates to the CEQA Guidelines including the incorporation of SB 743 modifications. The Guidelines' changes were approved by the Office of

Administrative Law and are now in effect. Specific to SB 743, Section 15064.3(c) states, “A lead agency may elect to be governed by the provisions of this section immediately. The provisions apply statewide as of July 1, 2020.

To help aid lead agencies with SB 743 implementation, the Governor’s Office of Planning and Research (OPR) produced the *Technical Advisory on Evaluating Transportation Impacts in CEQA*¹ (December 2018) that provides guidance about the variety of implementation questions they face with respect to shifting to a VMT metric. Key guidance from this document includes:

- VMT is the most appropriate metric to evaluate a project’s transportation impact.
- OPR recommends tour- and trip-based travel models to estimate VMT, but ultimately defers to local agencies to determine the appropriate tools.
- OPR recommends measuring VMT for residential and office projects on a “per rate” basis.
- OPR recommends that a per capita or per employee VMT that is fifteen percent below that of existing development may be a reasonable threshold. In other words, an office project that generates VMT per employee that is more than 85 percent of the regional VMT per employee could result in a significant impact. OPR notes that this threshold is supported by evidence that connects this level of reduction to the State’s emissions goals.
- OPR recommends that where a project replaces existing VMT-generating land uses, if the replacement leads to a net overall decrease in VMT, the project would lead to a less-than-significant transportation impact. If the project leads to a net overall increase in VMT, then the thresholds described above should apply.
- Lead agencies have the discretion to set or apply their own significance thresholds.

VMT Thresholds of Significance

In 2019, the El Dorado County Transportation Commission completed the *El Dorado County and City of Placerville SB 743 Implementation Plan*² (July 19, 2019) to support El Dorado County and the City of Placerville with implementation of SB 743, including the selection of VMT analysis methodology, setting thresholds of significance, and potential mitigation.

¹ Governor’s Office of Planning and Research. *Technical Advisory on Evaluating Transportation Impacts in CEQA*. December 2018. https://opr.ca.gov/docs/20190122-743_Technical_Advisory.pdf

² El Dorado County Transportation Commission. *El Dorado County and City of Placerville SB 743 Implementation Plan*. July 19, 2019. <https://www.edcgov.us/Government/dot/Documents/Transportation%20Planning/EDCTC%20SB743%20Implementation%20Plan.pdf>

With Resolution 141-2020³ (October 6, 2020), the Board of Supervisors of the County of El Dorado adopted VMT thresholds of significance for purposes of analyzing transportation impacts under CEQA.

The County's VMT thresholds consider the VMT performance of residential and office components of a project separately, using the efficiency metrics of VMT per capita and VMT per employee, respectively. For retail components of a project, the county-wide VMT effect is analyzed. The El Dorado County VMT thresholds of significance are summarized below for each of these components:

- Residential – 15% below baseline unincorporated countywide VMT per Capita
- Commercial Office – 15% below baseline unincorporated countywide VMT per Employee
- Commercial Retail – No net increase in VMT

VMT Estimation Methodology

Consistent with Resolution 141-2020, VMT estimation was conducted using the El Dorado County Travel Demand Forecasting Model (EDCTDM). The VMT estimation process generates estimates in a manner that is consistent with OPRs Technical Advisory and the selected VMT significance thresholds outlined above.

The following section from the Technical Advisory suggests that lead agencies should use VMT estimation methodologies that account for the “full extent of vehicle travel”.

Considerations for All Projects. Lead agencies should not truncate any VMT analysis because of jurisdictional or other boundaries, for example, by failing to count the portion of a trip that falls outside the jurisdiction or by discounting the VMT from a trip that crosses a jurisdictional boundary. CEQA requires environmental analyses to reflect a “good faith effort at full disclosure.” (CEQA Guidelines, § 15151.) Thus, where methodologies exist that can estimate the full extent of vehicle travel from a project, the lead agency should apply them to do so. Where those VMT effects will grow over time, analyses should consider both a project’s short-term and long-term effects on VMT.

To provide a full accounting of vehicle travel, the EDCTDM provides VMT estimates that include the VMT from intrazonal vehicle trips and trip length adjustments for the trips that enter or exit the area covered by the EDCTDM.

Intrazonal Trips and Trip Lengths

The VMT estimation process includes intrazonal trips in its estimates. Intrazonal trips are trips that have their origin and destination within the same traffic analysis zone (TAZ). Because these trips do not leave a TAZ, they are not assigned to the EDCTDM’s roadway network. Consequently, intrazonal trips cannot be

³ Board of Supervisors of the County of El Dorado Resolution 141-2020.
<https://www.edcgov.us/Government/dot/Documents/Transportation%20Planning/Executed%20Resolution%20141-2020.pdf>

directly derived from the EDCTDM's network and must be estimated to provide a more complete VMT analysis. The intrazonal trip lengths are estimated by calculating half of the shortest travel distance between a given TAZ and all the other TAZs, using the EDCTDM's midday assignment. The EDCTDM uses the following four assignment periods to develop a 24-hour travel assignment:

- AM3VS.NET – AM 3-Hour Assignment
- MDVS.NET – Midday 5-Hour Assignment
- P3V.NET – PM 3-Hour Assignment
- EVV.NET – Evening 13-Hour Assignment

The different assignment periods are used to account for the affect that congestion has on accessibility (i.e., the ability to travel between two locations). It typically takes longer to travel the same distance during peak periods than it does during other times of the day. The midday 5-hour assignment period is used to calculate intrazonal travel because there is generally less traffic and less congestion (i.e., compared to the AM or PM peak periods) and is more representative of average daily conditions.

Gateway Trip Length Adjustments

The EDCTDM includes a buffer area that extends along Highway 50 from El Dorado County into eastern Sacramento County, including the City of Folsom and City of Rancho Cordova. **Figure 1** shows the model area, including the TAZs that represent El Dorado County (purple), the buffer area (yellow), and the state highway system. The buffer area allows for more detailed modeling of travel interaction between El Dorado County and eastern Sacramento County. However, even with the buffer area, adjustments to the length of trips passing through the EDCTDM's gateway locations are necessary to account for the full length of trips throughout California.

Table 1 summarizes the average trip lengths for trips entering (XI) and exiting (IX) the EDCTDM developed using the California Statewide Travel Demand Model (CSTDm). Although not as detailed as the EDCTDM, the CSTDm can summarize the general patterns of trips made by El Dorado County residents and employees entering and leaving the County throughout California. The CSTDm scale makes it a useful tool to generate trip length estimates for trips entering or leaving the EDCTDM coverage area.

Because of the sample size limitations with the California Household Travel Survey (CHTS) data (i.e., only 163 recorded trips), trip length adjustments from the CSTDm are used. The average additional travel distance from the CSTDm shown in **Table 1** indicate the additional lengths added to the trips that pass through the EDCTDM's gateway locations.

Table 1: Average Trip Length Adjustments for Each Gateway Location

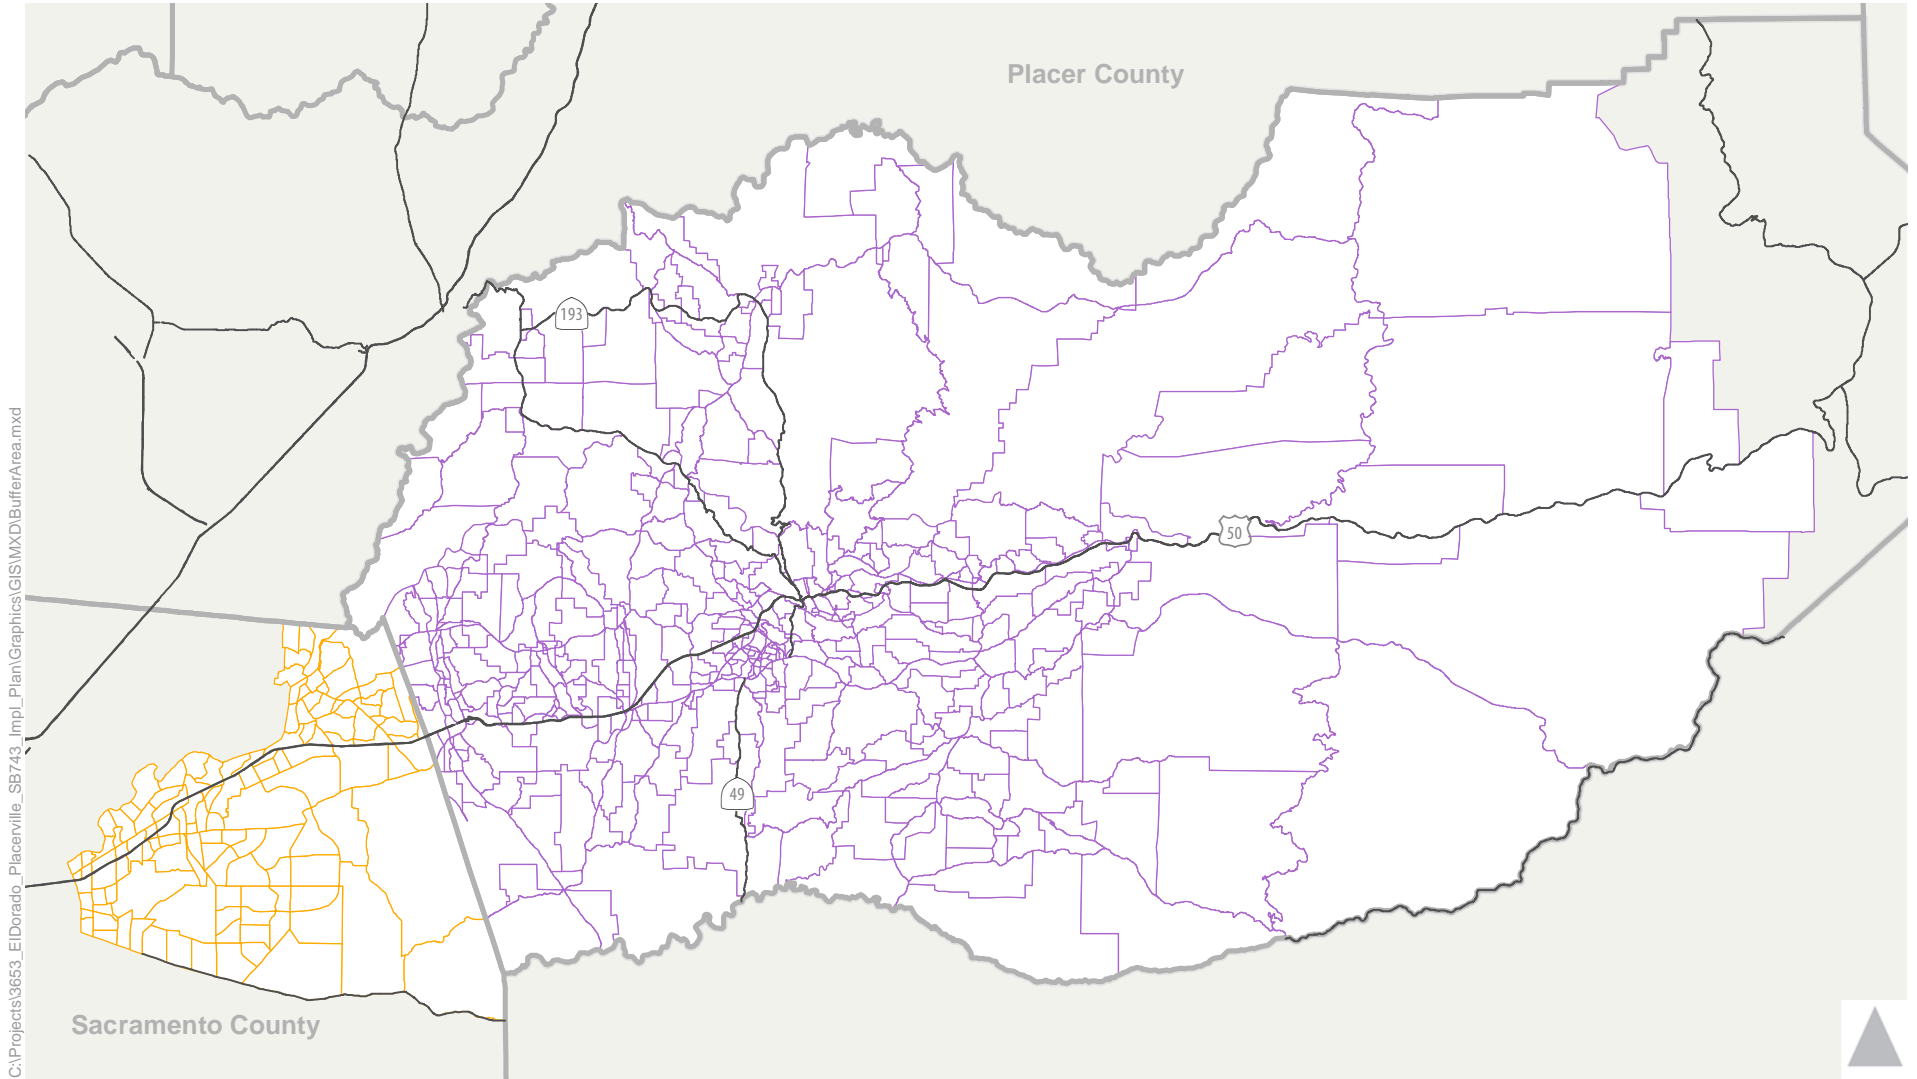

Gateway Location	Direction	Gateway Node ID	Average Additional Travel Distance (miles)	
			Internal to External (IX) Trips	External to Internal (XI) Trips
US 50	West	650	12.41	13.08
Dillard Road	South	651	4.11	3.96
Sloughhouse Road	South	652	0.00	0.00

-  Buffer Area
-  Regional Centerlines
-  SACOG Counties

Figure 1
El Dorado County Model (2018)
Traffic Analysis Zones within El Dorado County and the Buffer Area

Model-wide Network Refinements

The EDCTDM is a countywide model developed and maintained by the County for traffic analysis related to the General Plan and Traffic Impact Fee Program. Consistent with these applications, the model includes major transportation facilities, including County arterials like El Dorado Hills Boulevard and State facilities like US 50, and a TAZ system that is at a corresponding level of detail. The EDCTDM does not include local and collector roadways. Therefore, the EDCTDM may require refinement for different applications.

The 2017 California Regional Transportation Plan Guidelines (CTC, January 2017) provides guidance on the application of travel demand models. Specifically, that travel demand models should be at an appropriate scale relative to the analysis being conducted. Consistent with this guidance, additional roadway network and TAZ detail was added in El Dorado Hills north of US 50, south of Green Valley Road, east of Sophia Parkway, and west of El Dorado Hills Boulevard to better reflect actual travel time and distance between El Dorado Hills and the City of Folsom. **Figure 2** compares the traffic analysis zone and roadway network detail with and without modification.

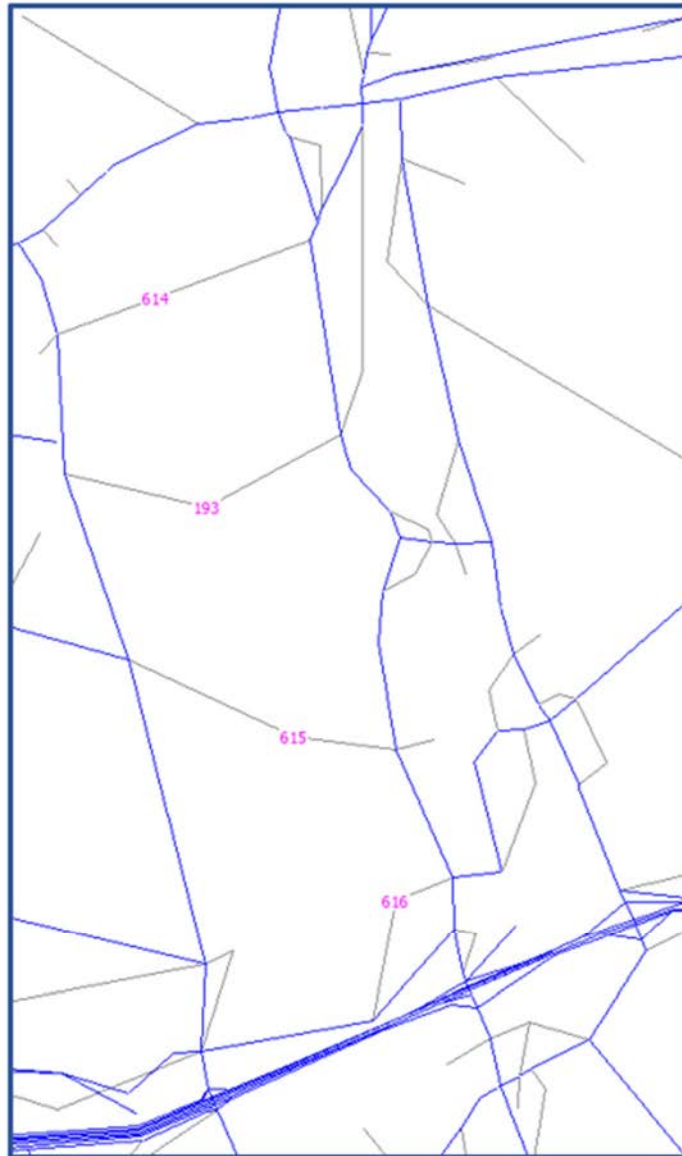

Without modification, the EDCTDM uses 4 TAZs to represent most of the land use in this area with local roadway access modeled using special model links, referred to as TAZ centroid connectors. TAZ centroid connectors provide access for the local development but not for other trips on the network. With this roadway network coding trip lengths are shorter for the land uses represented by the 4 TAZs.

The modified network increased the TAZ detail from 4 to 22 and added roadway links, instead of TAZ centroid connectors, for local access between El Dorado Hills and the City of Folsom in this area. The following public roadway connections were added between El Dorado Hills Boulevard and Sophia Parkway/Empire Ranch Road:

- North Connection: Brittany Way – Suffolk Way – Elmores Way
- North Central Connection: Olson Lane – Gillette Drive – Ridgeview Drive – Muse Drive – Mossridge Way – Powers Drive – Julie Ann Way – Beatty Drive – Alexandra Drive
- South Central Connection: Wilson Boulevard –Ridgeview Drive – Powers Drive – Montridge Way – Crestline Circle – Via Treviso – Via Barlogio – Hildebrand Circle – Woodhead Street
- South Connection: Wilson Boulevard (El Dorado Hills Boulevard to Saratoga Way)

Figure 2 – EDCTDM Model-Wide Network Refinements

Without Modification

With Modification

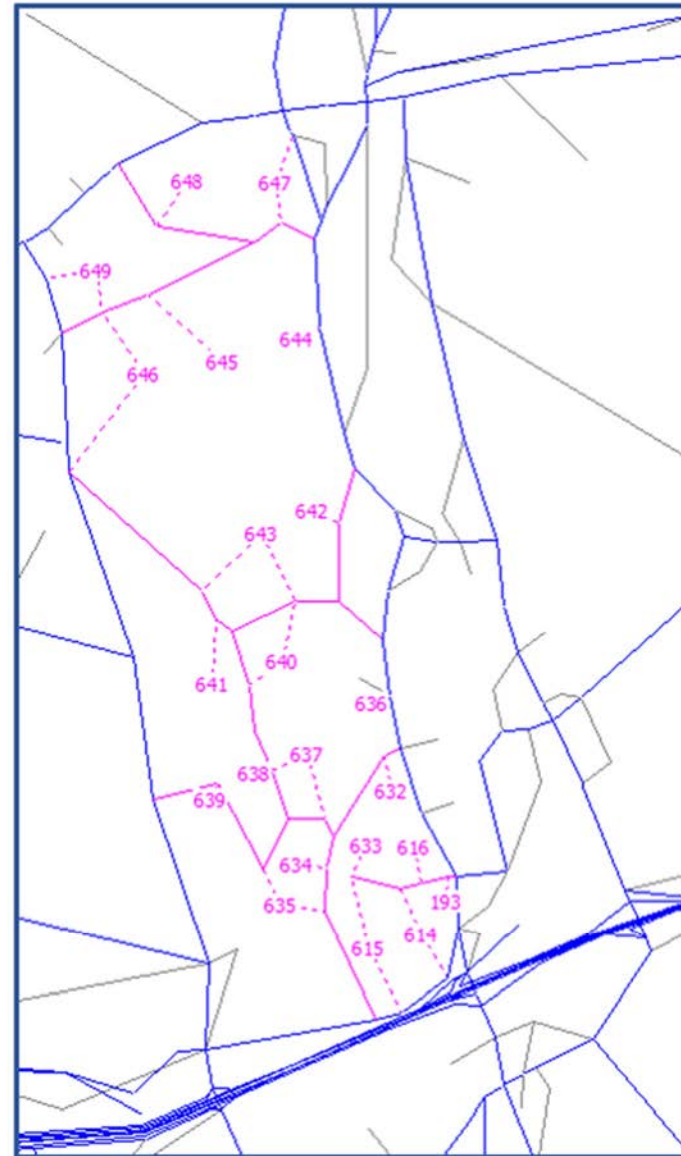

Table 2 compares the estimated travel time from the EDCTDM after modification to field measured travel times. As shown, the model's estimated travel time is consistent with and comparable to field measurements. Therefore, the model is more representative of actual travel times and distance than the EDCTDM prior to modification since the model did not include these connections.

Table 2: Travel Time Comparison (Model Estimate vs Field Measurement)			
Added Roadway Connection	Travel Time (minutes)		
	Model Estimate	Field Measurement	Difference (Model – Field)
North	3.3	3.0	+0.3
North Central	5.2	5.1	+0.1
South Central	4.4	4.7	-0.3
South	2.5	2.7	-0.2

The TAZ and roadway network modifications shown in **Figure 2** were made to both the Base Year (2018) and Cumulative Year (2040) EDCTDMs. The modified models were used for the analysis of the proposed project to maintain analysis consistency.

Table 3 compares the VMT efficiency metrics for residential and commercial office land uses in unincorporated El Dorado County with and without the roadway network refinements outlined above and on **Figure 2**. As shown, the VMT efficiency metrics for both residential and commercial office land use increased with the network refinement. The direction and magnitude of the change is reasonable and in the correct direction relative to the network refinements made.

Table 3: VMT Efficiency Metrics with Network Refinements				
Land Use	VMT Efficiency Metrics (Unincorporated El Dorado County)			
	Without Refinements	With Refinements	Difference	VMT Threshold (With Refinements)¹
2018				
Residential	22.5	22.7	+0.2	19.3
Commercial Office	12.8	13.0	+0.2	11.1
2040				
Residential	16.9	17.1	+0.2	14.5
Commercial Office	11.7	12.0	+0.3	10.2

Notes:

¹85% of Unincorporated El Dorado County VMT per Capita (Residential) and VMT per Employee (Commercial Office)

Study Area Network Refinements

In addition to the model-wide network edits discussed above, the study area required refinement of the TAZ system to better reflect the project land use and geography. In the study area, the EDCTDM includes one TAZ that models the residential land use served by Marble Ridge Road and Marble Mountain Road (west of the VMVSP). Three new TAZs were added in the VMVSP to represent the project, one TAZ for each land use component (i.e., residential, commercial office, and commercial retail). Figure 3 shows the study area network with and without the network refinements.

Figure 3 – EDCTDM Study Area Network Refinements

Without Modification

With Modification

The following steps outline the method we used to forecast VMT under existing and cumulative conditions:

- Existing Conditions (2018) – For existing conditions (i.e., baseline conditions), the base year model land use and transportation network were used to estimate baseline (2018) average VMT per capita and average VMT per employee for unincorporated El Dorado County.

For existing plus project conditions, the project’s land use was added to the modified model, increasing the base year population and employment. Project-generated average VMT per capita and VMT per employee were calculated.

- Cumulative Conditions (2040) – For cumulative conditions, the future year model was used to estimate cumulative (2040) average VMT per capita and average VMT per employee.

For cumulative plus project conditions, the project’s land use was added to the modified model, increasing the cumulative year population and employment. Project-generated average VMT per capita and VMT per employee were calculated.

VMT Calculation for Each TAZ

VMT is estimated using a three-step process. In the first step, travel distance between each pair of TAZs for using the loaded networks for the four model time periods (AM Peak Period, Midday Period, PM Peak Period, and Evening Period). Using the loaded network accounts for any increases in trip distance that may result from traffic congestion. In this process, the additional trip lengths associated with the model gateways are added to the trip length estimates. The distance of intrazonal trips is estimated as outlined above.

The second step of the process calculates the VMT for travel between each TAZ pair. The number of vehicle trips modeled between each TAZ pair is multiplied by the trip lengths to estimate the VMT associated with the travel between each TAZ pair for each time period. The VMT from the intrazonal trips is also included in the VMT estimates.

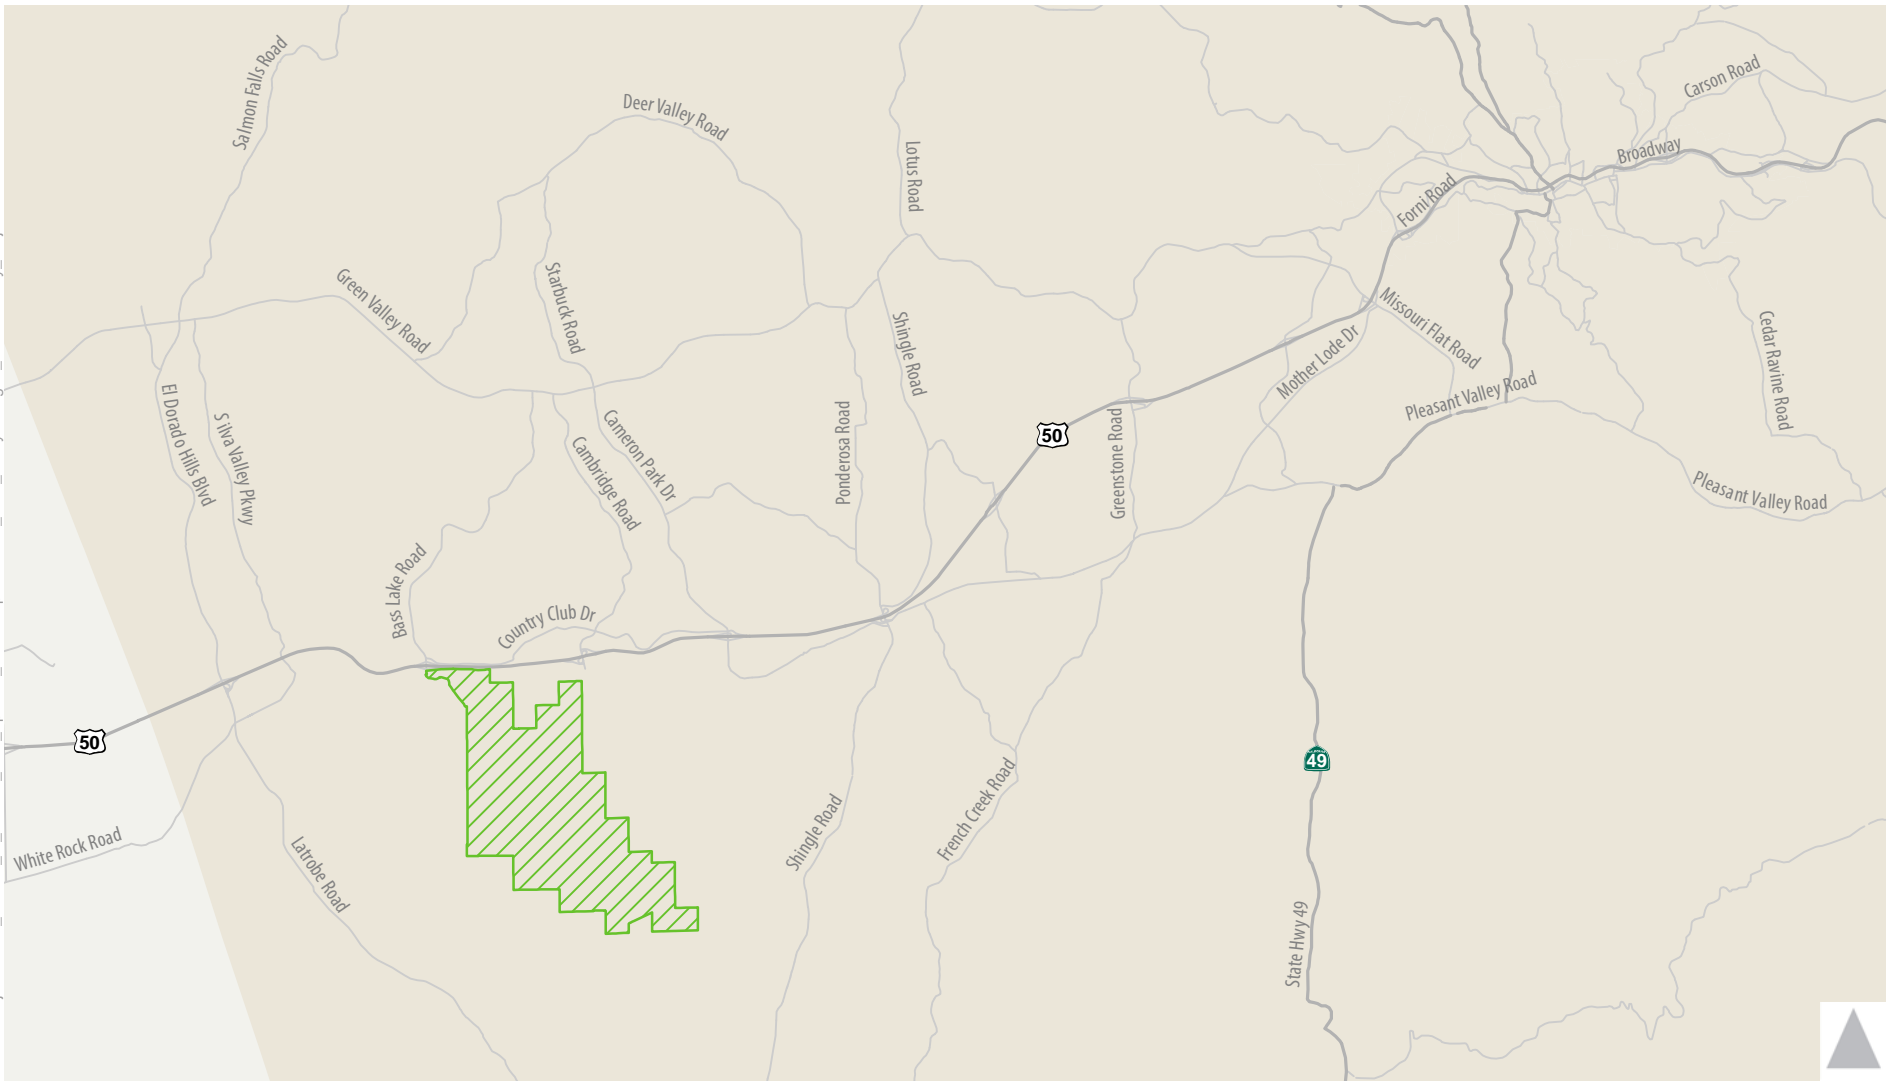

The third step estimates the home-based and home-based work VMT. These estimates are calculated by determining the percentage of vehicle productions and attractions by trip purpose and direction (departures and returns). These percentages are then applied to the total VMT estimates, to determine the VMT by trip purpose and direction. The home-based VMT summarizes VMT by the origin TAZ. The home-based work VMT summarizes VMT by the destination TAZ. The use of home-based and home-based work VMT allows independent analysis of residential and commercial project components.

Project Summary

Figure 4 shows the location of the project. As proposed, the project includes residential, commercial, agriculture, park and open space land use. **Table 4** summarizes the project’s trip generating land uses.

Table 2: Village of Marble Valley Specific Plan Land Use			
Land Use			Total
Category	Units		
Residential	Single Family	Dwellings	2,735
	Multi-Family		501
	Total		3,236
Non-Residential	Office Park	Square Feet	375,000
	Village Commercial	Square Feet	100,000
	Agriculture Tourism	Acres	42

VMT Threshold Exceeded?				Yes

Table 6: Village of Marble Valley Specific Plan's VMT – Commercial Office Component				
Scenario	Analysis Geography	VMT	Total Employment	VMT per Employee
2018 Baseline	Unincorporated El Dorado County	428,483	33,076	13.0
2018 Baseline Threshold (85% of Unincorporated El Dorado County Total Average VMT per Employee)				11.1
2018 Baseline Plus Project	Project Area	12,554	1,704	7.4
VMT Threshold Exceeded?				No
2040 Baseline	Unincorporated El Dorado County	675,594	56,413	12.0
2040 Baseline Threshold (85% of Unincorporated El Dorado County Total Average VMT per Employee)				10.2
2040 Baseline Plus Project	Project Area	11,775	1,704	6.9
VMT Threshold Exceeded?				No

Table 7: Village of Marble Valley Specific Plan's VMT – Commercial Retail Component		
Scenario	Analysis Geography	VMT
2018 Baseline Plus Project	Unincorporated El Dorado County	3,277,660
2018 Baseline Plus Project No Retail		3,282,876
Difference (With Retail – Without Retail)		-5,216
2018 Baseline Threshold (No Net Increase in VMT)		-
VMT Threshold Exceeded?		No
2040 Baseline Plus Project	Unincorporated El Dorado County	3,256,081
2040 Baseline Plus Project No Retail		3,260,265
Difference (With Retail – Without Retail)		-4,184
2040 Baseline Threshold (No Net Increase in VMT)		-
VMT Threshold Exceeded?		No

As shown, the project’s VMT per Capita for the residential component would exceed the VMT threshold under existing and cumulative conditions. Therefore, the project’s impact on VMT would be significant.

Mitigation

Shifting 25,000 square feet of commercial offices land use to commercial retail land use would mitigate the impact of the residential component of the project. The shift would result is about 125,000 square feet of commercial retail and about 350,000 square feet of commercial office land use.

Table 8 summarizes the VMT analysis for the residential with the mitigation outlined above. As shown, implementation of the proposed mitigation would reduce VMT per Capita for the residential component to a level less than established threshold of 85% of Unincorporated El Dorado County VMT per Capita. Therefore, with this mitigation the impact would be reduced to a less than significant level.

Table 8: Village of Marble Valley Specific Plan's VMT – Residential Component (With Mitigation)				
Scenario	Analysis Geography	VMT	Total Population	VMT per Capita
2018 Baseline	Unincorporated El Dorado County	3,088,005	136,108	22.7

DEER CREEK WASTEWATER TREATMENT PLANT EXPANSION PROJECT EIR

MITIGATION MONITORING PROGRAM

INTRODUCTION

The California Environmental Quality Act (CEQA) (Public Resources Code Section 21000 et seq., as amended by Chapter 1232) requires all state and local agencies to establish monitoring or reporting programs for projects approved by a public agency whenever approval involves the adoption of either a "mitigated negative declaration" or specified environmental findings related to environmental impact reports.

The mitigation monitoring program contained herein is intended to satisfy the requirements of CEQA as they relate to the Final Environmental Impact Report (EIR) for the Deer Creek Wastewater Treatment Plant (WWTP) Expansion Project prepared by the El Dorado Irrigation District (EID). This MMP is intended to be used by EID staff and mitigation monitoring personnel to ensure compliance with mitigation measures during project implementation. Mitigation measures identified in this MMP were developed as part of the EIR process for the proposed project.

The Deer Creek Wastewater Treatment Plant Expansion Project EIR presents a detailed set of mitigation measures that will be implemented throughout the lifetime of the project. Mitigation is defined by CEQA as a measure which:

- Avoids the impact altogether by not taking a certain action or parts of an action.
- Minimizes impacts by limiting the degree or magnitude of the action and its implementation.
- Rectifies the impact by repairing, rehabilitating, or restoring the impacted environment.
- Reduces or eliminates the impact over time by preservation and maintenance operations during the life of the project.
- Compensates for the impact by replacing or providing substitute resources or environments.

The intent of the MMP is to ensure the effective implementation and enforcement of adopted mitigation measures and permit conditions. The MMP will provide for monitoring of construction activities as

necessary, in-the-field identification and resolution of environmental concerns, monitoring of daily operations of the wastewater treatment plant, and proper reporting to EID staff.

COMPLIANCE CHECKLIST

Monitoring and documenting the implementation of mitigation measures will be coordinated by EID.

Table 1 of this report identifies the mitigation measure, the monitoring action for the mitigation measure, the responsible party for the monitoring action, and timing of the monitoring action. EID will be responsible for fully understanding and effectively implementing the mitigation measures contained within the MMP to ensure that identified significant impacts have been avoided or mitigated to a level of less than significant.

FIELD MONITORING OF CONSTRUCTION

During expansion of the wastewater treatment plant, EID's construction inspector will be responsible for field monitoring of mitigation measure compliance. The inspector will report to EID and will be thoroughly familiar with the plans and requirements set forth in the permit conditions and the MMP. In addition, the inspector will be familiar with construction contract requirements, construction schedules, standard construction practices, and mitigation techniques. In order to track the status of mitigation measure implementation, field monitoring activities will be documented on compliance monitoring report worksheets. The time commitment of the inspector will vary depending on the intensity and location of construction. Aided by **Table 1**, the inspector will be responsible for the following activities:

- On- site, day-to-day monitoring of construction activities.
- Reviewing construction plans and equipment staging/access plans to ensure conformance with adopted mitigation measures.
- Ensuring contractor knowledge of and compliance with all appropriate permit conditions and the MMP.
- Evaluating the adequacy of construction impact mitigation measures and proposing improvements to the contractors and EID staff.
- Having the authority to require correction of activities that violate project permit conditions or mitigation measures, or that represent unsafe or dangerous conditions. The inspector shall have the ability and authority to secure compliance with the conditions or standards through the EID General Manager, if necessary.
- Acting in the role of contact for adjacent property owners or any other affected persons who wish to register observations of violations of project permit conditions or mitigation measures, or unsafe or dangerous conditions. Upon receiving any complaints, the inspector shall immediately contact the construction contractor representative. The inspector shall be

responsible for verifying any such observations and for developing any necessary corrective actions in consultation with the construction representative and EID.

- Maintaining prompt and regular communication with EID, other appropriate County agencies, or pertinent resource agencies (i.e., California Department of Fish and Game [CDFG], U.S. Fish and Wildlife Service [USFWS], U.S. Army Corps of Engineers [COE]).
- Obtaining assistance as necessary from technical experts, such as archaeologists, botanists, wildlife biologists, and wetland scientists, in order to develop site-specific procedures for implementing the mitigation measures.
- Maintaining a log of all significant interactions, violations of permit conditions or mitigation measures, and necessary corrective measures.

In the event that resolution of disputes between the public and/or governmental agencies and the project contractors regarding adherence to permit conditions and mitigation measures is not resolved by the inspector, the dispute shall be referred to the EID General Manager for resolution.

MONITORING OF WWTP OPERATIONS

The primary responsibility for carrying out mitigation measures applying to operation of the plant will lie with EID. Appointed staff will be thoroughly familiar with operational procedures and the MMP requirements. Ultimate enforcing responsibilities for corresponding on-going, operational-type mitigation measures lie with, but are not limited to, the Central Valley Regional Water Quality Control Board (RWQCB), El Dorado County Department of Environmental Management, California Department of Fish and Game, and the El Dorado Air Pollution Control District. Aided by **Table 1**, EID's appointed monitor of mitigation measure implementation will be responsible for the following activities:

- Ensuring staff knowledge of and compliance with all appropriate permit conditions and the MMP.
- Should a copper bioavailability study indicate copper-related problems, ensuring sufficient monitoring of addition of measures to reduce copper levels in wastewater prior to discharge.
- As enforced by El Dorado County Department of Environmental Management, continually updating its hazardous materials inventory and Emergency Response Plan and ensuring that EID remains current in staff hazardous materials training.
- Maintaining EID's compliance with the State Health and Safety Code.
- Ensuring updated compliance with the appropriate aquatic life criteria of the pertinent contaminant control regulations as they are developed.
- Coordinating participation in local land use activities and informing area developers of their disclosure responsibilities in regards to odor impacts.

- Coordinating implementation of mitigation measures targeted at noise reduction.
- Ensuring compliance with regulatory agency standards in regards to odor control and development of an odor control plan.
- Maintaining prompt and regular communication with the appropriate County agencies, or pertinent resource agencies (i.e., California Department of Fish and Game, El Dorado Air Pollution Control District, and State Water Resources Control Board).
- Maintaining a log of all significant interactions, violations of permit conditions or mitigation measures, and necessary corrective measures.

TABLE 1
MITIGATION MONITORING PROGRAM

Mitigation Measure	Implementing Responsibility	Monitoring Responsibility	Timing	Compliance Standards	Verification of Compliance (Initials & Date)
4.3 HYDROLOGY AND WATER QUALITY					
<p>4.3.6a EI Dorado Irrigation District (EID) shall prepare a copper bioavailability study to determine the fraction of discharged copper in toxic form. Should the bioavailability study determine there is a significant adverse risk to representative sensitive aquatic species, then EID shall implement mitigation measures to reduce the level of risk to Deer Creek aquatic resources to a level of less than significant. Such mitigation measures could include:</p> <ul style="list-style-type: none"> ▪ Chemical addition of additives which enhance the complexing of copper in the wastewater treatment train prior to discharge. ▪ Implement an Industrial Pre-Treatment Program targeting the sources of copper within the service area of the Deer Creek WWTP. The program will identify primary sources of copper and means of controlling copper prior to discharge into the sanitary sewer system through any number of best management practices and best available control technologies to be implemented by the individual sources through sanitary sewer discharge permits. 	EID	Regional Water Quality Control Board (RWQCB)	As required by NPDES permit.	Acceptance of study by RWQCB.	
<p>4.3.6b EID shall implement necessary controls at the Deer Creek WWTP to meet the freshwater aquatic life criteria of the pertinent contaminant control regulations as future aquatic life criteria are developed and modified. Future design of the Deer Creek WWTP shall allow accommodation of necessary treatment facilities required to meet foreseeable future effluent discharge criteria.</p>	EID	RWQCB	Ongoing	Compliance with NPDES permit	
4.4 AIR QUALITY					
<p>4.4.2a EID shall require its contractors to demonstrate to the EI Dorado APCD their compliance with rule 223- Fugitive Dust of the EI Dorado APCD Rules and Regulations Handbook. A fugitive dust prevention and control plan describing the proposed Best Management Practices (BMPs) to be implemented for the control of fugitive dusts throughout the construction phase shall</p>	EID	EI Dorado APCD	Prior to construction	Site inspection to verify that measures are being implemented	

TABLE 1
MITIGATION MONITORING PROGRAM (Continued)

Mitigation Measure	Implementing Responsibility	Monitoring Responsibility	Timing	Compliance Standards	Verification of Compliance (Initials & Date)
be prepared and reviewed by the APCD prior to initiation of dust creating construction activities, including site grading, excavation, and/or demolition.					
<p>4.4.2b EID shall require construction contract documents to state that all fuel combustion construction equipment (both stationary and mobile) be tuned for optimal performance during all construction activities. In addition and to the extent possible, EID and its contractors shall implement the following measures:</p> <ul style="list-style-type: none"> ▪ Retard diesel engine injection timing by two to four degrees. ▪ Use electricity from power poles rather than by temporary gasoline or diesel generators. ▪ Use reformulated, low-emission diesel fuel. ▪ Use catalytic converters on gasoline-powered equipment. ▪ Do not leave inactive construction equipment idling for prolonged periods (i.e., more than two minutes). ▪ Schedule construction activities and material hauls that affect flow to off-peak hours. ▪ Configure construction parking to minimize traffic interference. 	EID	EID	Prior to bid	Verification of contract wording	
<p>4.4.2c EID shall encourage the use of low- emission construction equipment and shall encourage the use of feasible construction employee transportation alternatives such as ridesharing.</p>	EID	EID	Throughout construction	Verify compliance	
<p>4.4.3 Since the impact was found to be less than significant, mitigation is not required. However, the following measures are suggested to reduce energy consumption and any associated emissions connected with the production of energy at off-site power generation facilities.</p> <ul style="list-style-type: none"> ▪ To the extent reasonably feasible, the District and its contractors shall implement the following measures: ▪ Tree planting in excess of that already required. Retain existing trees to reduce building heating/cooling needs. 	EID	EID	Prior to bid and throughout construction	Verify installation and compliance	

TABLE 1
MITIGATION MONITORING PROGRAM (Continued)

Mitigation Measure	Implementing Responsibility	Monitoring Responsibility	Timing	Compliance Standards	Verification of Compliance (Initials & Date)
<ul style="list-style-type: none"> ▪ Improve the thermal integrity of buildings, and reduce the thermal load with automated time clocks or occupant sensors. ▪ Use energy-efficient, low-sodium parking lot and street lights. ▪ Install lamps that give the highest light output per watt of electricity consumed. ▪ Control mechanical systems or equipment with time clock or computer systems. 					
<p>4.4.4 Since the impact was found to be less than significant, mitigation is not required. However, the following measures are suggested to reduce energy consumption and any associated emissions connected with the production of energy at off-site power generation facilities. To the extent reasonably feasible, the District and its contractors shall implement the following measures:</p> <ul style="list-style-type: none"> ▪ Tree planting in excess of that already required. Retain existing trees to reduce building heating/cooling needs. ▪ Improve the thermal integrity of buildings, and reduce the thermal load with automated time clocks or occupant sensors. ▪ Use energy-efficient, low-sodium parking lot and street lights. ▪ Install lamps that give the highest light output per watt of electricity consumed. ▪ Control mechanical systems or equipment with time clock or computer systems. 	EID	EID	Prior to bid and throughout construction	Verify installation and compliance	
<p>4.4.6a EID shall design and build facilities that can be retrofitted in the future with odor control mechanisms. Odor control should target the chief odor sources: head works, primary treatment processes, and sludge dewatering facilities. Odor control mechanisms could include, but should not be limited to, the following measures:</p>	EID	EID	During design and construction	Plan review and site inspection to verify that measures are being implemented	

TABLE 1
MITIGATION MONITORING PROGRAM (Continued)

Mitigation Measure	Implementing Responsibility	Monitoring Responsibility	Timing	Compliance Standards	Verification of Compliance (Initials & Date)
<ul style="list-style-type: none"> ▪ Sealed and scrubbed headworks, ▪ Chemical treatment of influent prior to entrance at the headworks, and ▪ Enclosed sludge handling areas. <p>Implementation of the odor control mechanisms shall occur, when deemed necessary, in response to odor generation problems or future potential odor complaints.</p>					
4.4.6b EID shall continue to operate the Deer Creek WWTP in a fashion prohibiting the stockpiling of dewatered sludge in uncontained outdoor open areas.	EID	EID	Ongoing	Site inspection to verify that measures are being implemented	
4.4.6c EID shall implement an odor complaint monitoring program to gauge the need and timing of additional odor control measures at the treatment plant. Such a monitoring program shall consist of a standard complaint logging procedure, including date, time, and origin of complaint along with a description of the atmospheric conditions present during the time of the complaint. The complaint shall be followed up by an inspection of the treatment plant to determine the source of the nuisance odor and any actions taken to remedy the problem. The complaint log will be maintained on-site for at least five years.	EID	EID	On-going	Verification of implemented odor complaint monitoring program	
4.4.6d EID shall comply with the direction of the appropriate regulatory agencies regarding odor control.	EID	EID	On-going	Verify compliance	
4.4.6e EID shall actively participate in land use planning activities in the vicinity of the Deer Creek WWTP and publicly comment on future developments proposed in the vicinity of the treatment plant.	EID	EID	On-going	Verified participation in future land use planning activities	
4.4.6f EID, as a condition of sewer hook-up and annexation, shall require the applicant of the planned Marble Valley subdivision to notify all prospective owners of the potential for significant odor impacts associated with WWTP operations during individual lot sale proceedings.	EID	EID	Prior to sewer hookup and annexation	Verification of written agreement with said applicant to disclosure of odor impacts	

TABLE 1
MITIGATION MONITORING PROGRAM (Continued)

Mitigation Measure	Implementing Responsibility	Monitoring Responsibility	Timing	Compliance Standards	Verification of Compliance (Initials & Date)
4.5 GEOLOGY, SOILS, AND SEISMICITY					
4.5.2a Prior to project construction, EID shall require that specific Best Management Practices (BMPs) for erosion control will be implemented throughout the construction phase for all grading and excavation activities until successful surface stabilization has been achieved. Typical BMPs include hydroseeding, geotextiles and mats, and straw bale or sand bag barriers.	EID	EID	Throughout construction	Site inspection to verify that measures are being implemented	
4.5.2b Minimize elapsed time between excavation and reuse of excavated material on-site and provide adequate stockpile coverage or watering during the entire storage period.	EID	EID	Throughout construction	Site inspection to verify that measures are being implemented	
4.6 BIOLOGICAL RESOURCES					
4.6.1a EID shall retain a qualified wildlife biologist to conduct a survey for nesting raptors (in March or April) at the project site prior to construction activity (i.e., grading). Active raptor nests located within 500 feet of construction activity shall be mapped.	EID	EID	Prior to construction	Verification of monitoring results	
4.6.1b If active raptor nests are located on or within 500 feet of an active or scheduled construction site, then appropriate buffer zones shall be established in consultation with the CDFG, and construction activities shall be prohibited within this buffer zone until the end of the nesting season (April through July) or until the young have fledged. A qualified wildlife biologist shall monitor the nest to determine when the young have fledged and submit weekly reports to the CDFG throughout the nesting season.	EID	California Department of Fish and Game and EID	Prior to construction	Submission of weekly reports to CDFG	
4.6.1c If necessary, identified nest trees may only be removed prior to the onset of the nesting season (March) or after young have fledged (late July).	EID	EID	Prior to construction	Verify compliance	
4.6.2a The preferred mitigation for VELB is avoidance as described in the most recent mitigation guidelines for VELB (USFWS, 1996). Avoidance includes, among other requirements, fencing all elderberry shrubs at least 20 feet from the shrub dripline and protection of the area within 100 feet of the shrubs following construction. If all avoidance measures outlined in the mitigation guidelines are followed, no further mitigation is necessary.	EID	US Fish and Wildlife Service and EID	Prior to construction	Site inspection to verify that measures are being implemented/ Submission of VELB mitigation plan to USFWS	

TABLE 1
MITIGATION MONITORING PROGRAM (Continued)

Mitigation Measure	Implementing Responsibility	Monitoring Responsibility	Timing	Compliance Standards	Verification of Compliance (Initials & Date)
If the shrub cannot be avoided, a survey of the shrub to be removed should be conducted by a qualified biologist to determine if any VELB exit holes are present. EID should then enter into formal consultation with the USFWS and develop a VELB mitigation plan based on the 1996 guidelines.					
4.6.2b To ensure protection of the avoided elderberry shrub, highly visible temporary fencing shall be placed at a distance which is at 20 feet from the diameter of the elderberry shrub. This exclusionary fencing shall remain in place until all construction work is complete. At no time during construction may vehicles, wastes, or construction materials be placed inside of the exclusionary fencing. This protective measure shall be included in the construction plan and specifications.	EID	EID	Prior to construction	Site inspection to verify that measures are being implemented	
4.6.3 EID shall retain a qualified wildlife biologist to conduct a survey to identify active yellow warbler and yellow-breasted chat nests within a 350-foot radius of the project site prior to construction activities. This survey may be conducted in conjunction with the raptor nest survey (Mitigation Measure 4.6.2a). If no active nests are found, construction may proceed. In the event that an active yellow warbler or yellow-breasted chat nest are observed on or within 350 feet of an active or scheduled construction site, then appropriate buffer zones shall be established in consultation with the CDFG, and construction activities shall be prohibited within this buffer zone until the end of the nesting season (March to early August) or until the young have fledged. A qualified wildlife biologist shall monitor the nest to determine when the young have fledged and submit weekly reports to the CDFG throughout the nesting season. If necessary, identified nest trees may only be removed prior to the onset of the nesting season (March) or after young have fledged (early August).	EID	California Department of Fish and Game and EID	Prior to construction	Verification of monitoring results	
4.6.7 EID shall include provisions in all construction contracts for the proposed project that prohibit construction employee parking in undesignated areas. In addition, EID shall erect exclusionary fencing between the existing access road and open meadow area located between the effluent channel and Deer Creek to discourage workers from parking in this area.	EID	EID	Throughout construction	Site inspection to verify that measures are being implemented	

TABLE 1
MITIGATION MONITORING PROGRAM (Continued)

Mitigation Measure	Implementing Responsibility	Monitoring Responsibility	Timing	Compliance Standards	Verification of Compliance (Initials & Date)
4.7 NOISE					
4.7.3a Future project level design of the Deer Creek WWTP to the maximum 10.8-mgd capacity shall incorporate the best available noise attenuating technologies and noise barriers such that a noise level measurement taken 150 feet beyond the Deer Creek WWTP fenceline would not exceed 58 dBA, L_{eq} , a noise level performance standard that can be reasonably assumed to ensure El Dorado County Noise Element nighttime noise standard compliance. Such technologies shall focus on the design of acoustical enclosures for stationary noise sources such as pumps, motors, and blowers; the use of inherently quieter treatment equipment, when available; and the use of soundwalls, if necessary.	EID	EID	On- going	Site inspection to verify that measures are being implemented	
4.7.3b EID shall evaluate WWTP activities that generate noise and implement policies targeted at reducing noise during these activities. Such an evaluation shall include the review of current noise attenuating practices such as keeping equipment building doors closed at all times.	EID	EID	On- going	Site inspection to verify that measures are being implemented	
4.8 HAZARDOUS MATERIALS / PUBLIC HEALTH					
4.8.2a EID shall continue to update its Deer Creek WWTP hazardous materials inventory and Emergency Response Plan throughout the phased expansion process, thus ensuring that the plan and inventory is accurate and relevant at all times. Updates shall be conducted pursuant to the guidelines provided by EID's administering agency: the El Dorado County Department of Environmental Management. The updated inventory and emergency plans shall be written to comply with the requirements of Section 6.95 of the State Health and Safety Code.	EID	El Dorado County Department of Environmental Management	On- going	Updated Deer Creek WWTP hazardous material inventory and Emergency Response Plan	
4.8.2b EID shall consult with the El Dorado County Department of Environmental Management during phased expansion to ensure that the Deer Creek WWTP is current with all its responsibilities concerning hazardous materials and their inventory, handling and emergency response training, and complaint with all relevant sections of the State Health and Safety Code.	EID	El Dorado County Department of Environmental Management	On- going	Verify compliance	

TABLE 1
MITIGATION MONITORING PROGRAM (Continued)

Mitigation Measure	Implementing Responsibility	Monitoring Responsibility	Timing	Compliance Standards	Verification of Compliance (Initials & Date)
4.8.4a EID shall consult and work with the El Dorado County Department of Environmental Management, the El Dorado County Fire Department, and the Marble Valley Development to design, install, or modify an appropriate site access road that would provide adequate routes for emergency entrance and egress to existing and future proposed (3.6 mgd and 10.8 mgd) Deer Creek WWTP facilities, taking into consideration construction activities. Deer Creek WWTP emergency response plans should be revised accordingly to take advantage of any new or modified access points.	EID	EID	On- going	Development of adequate routes for emergency ingress and egress to facilities	
4.8.4b EID shall ensure through contract documents, that all contractors and subcontractors are aware and understand their responsibilities in an emergency situation, and that contractors and subcontractors keep all designated evacuation and emergency response routes free of equipment or materials that would hinder or impede a timely emergency response.	EID	EID	On- going	Execution of contract agreements with contractors	
4.9 AESTHETIC RESOURCES					
4.9.2a Additional outdoor light fixtures shall be limited to low- pressure sodium lamps. High- intensity discharge light fixtures, including, but not limited to raw halide, mercury, and high- pressure sodium will be prohibited.	EID	EID	On-going	Site inspection to verify that measures are being implemented	
4.9.2b Additional outdoor light fixtures will be designed in such a way that no light rays are emitted directly from the fixture at angles above the horizontal plane and sideway light emissions are 20 percent below the horizontal plane. Additional lighting fixtures shall be limited to safety and security purposes.	EID	EID	On- going	Site inspection to verify that measures are being implemented	
4.10 TRAFFIC AND CIRCULATION					
4.10.1 EID shall ensure that roadways damaged by the project are returned to pre- project conditions by implementing the following measures: <ul style="list-style-type: none"> ▪ Prior to construction activities, a pre- project survey of project area roadways shall be performed with El Dorado County officials and private roadway owners to determine existing roadway conditions. 	EID	EID, El Dorado County, and private roadway owners	On-going	Site inspection to verify that measures are being implemented	

TABLE 1
MITIGATION MONITORING PROGRAM (Continued)

Mitigation Measure	Implementing Responsibility	Monitoring Responsibility	Timing	Compliance Standards	Verification of Compliance (Initials & Date)
<ul style="list-style-type: none"> ▪ A post- project survey of project traveled roadways shall be performed with El Dorado County officials and private roadway owners to determine if any damage has occurred from construction activities. If damage has occurred, EID shall be responsible for repairing the damage to the satisfaction of El Dorado County and the private roadway owner. 					
<p>4.11 CULTURAL RESOURCES</p>					
<p>4.11.1 In the event that any prehistoric or historic subsurface cultural resources are discovered during construction- related earthmoving activities, all work within 50 feet of the resources shall be halted and EID shall consult with a qualified archaeologist to assess the significance of the find. This provision will be included in all construction contracts awarded by EID. If any find is determined to be significant by the qualified archaeologist, then representatives of EID and the qualified archaeologist would meet to determine the appropriate course of action to avoid impacts to the find. If the discovery includes human remains, Section VII of CEQA guidelines Appendix K shall be followed, requiring coordination with the Native American Heritage Commission if the human remains are of Native American origin. In addition, the El Dorado County Coroner shall be contacted. All significant cultural materials recovered shall be subject to scientific analysis, professional museum curation, and a report prepared by the qualified archaeologist according the current professional standards.</p>	EID	EID	Prior to construction	Site inspection to verify that measures are being implemented

Executive Summary

A review of the expected fire behavior in the interface of the Marble Valley development indicates that the fire behavior could produce extreme fire behavior, and as such, risk reduction measures will be necessary. Many of these risk reduction measures are required by the State and Local fire/building regulations, fire department standards, and guidelines, and by risk reduction measures already considered and applied by the development review process. Fire behavior modeling predicts that there will be varied timeframes for evacuation of the Project Site under fire scenarios where the fire is burning into the community from an adjacent area. Each scenario has its own set of parameters. Where fires are initialized within the Project Site or near its boundary, the fire incident command and control may have to determine if the population will be moved or “sheltered in place.”

The proposed community with its increased built-in fire protection features (defensible space, fuel modification, hardening of the structures and required maintenance), placement of the structures on the topography, overall orientation to the fuels, wind, and slope and nested (safe center) configuration would be a candidate for a “shelter in place” decision. While “shelter in place” is never a first option, history shows us that moving populations, once the fire has arrived, has increased risk, and should not be attempted when safe alternatives exist.

The configuration of the Project Site, the placement of the structures and features on the topography and the nature of the wildland fuels surrounding the project create conditions where the fire will travel at great speeds when wind, slope and fuel align but all of the access points are not impacted by fire at the same time.

The fire behavior static modeling in this report with flame lengths of up to 55’ under the worst-case scenario would be protected by compliance with the Fire Department fuel modification/defensible space standards. Fuel modification/defensible space is designed to reduce and change the fuel types as the combustible vegetation gets closer to the structure. As a “rule of thumb,” two times the maximum flame length is adequate protection from radiant heat in a hardened structure. These distances also protect from direct flame contact (a distance greater than the flame length by a factor of two) and convected heat (less impactful than the radiant heat distance as discussed previously). The structure hardening (including ember intrusion projection) protects from embers and brands which may travel long distances under worst-case conditions.

The configuration of the Project Site development areas, the increased number of evacuation alternatives and the enhance protection features within the building construction and defensible space of the Project Site creates the conditions necessary to allow the resident to have viable options for all fire scenarios in the event that the community is impacted by a wildland fire. This report will be used as the basis for fire behavior assumptions in the evacuation modeling for the Project Site.

Introduction

The Village of Marble Valley Specific Plan (VMVSP, also referred to herein as the Project Site) is a proposed master-planned community by Marble Valley Company, LLC, located in the historic Marble Valley in the western foothills of El Dorado County. The VMVSP encompasses approximately 2,341 acres south of U.S. Highway 50, east of Bass Lake Road and west of Cambridge Road. The Specific Plan features a variety of residential types supported by employment, commercial, and recreational uses accessible to the public, including a village center, schools, vineyards, wine center, and historic park. The Specific Plan incorporates contemporary planning principles through a series of integrated land uses and transportation options, clustering a majority of the development footprint along a one-mile core with interconnecting trails and open spaces.

Purpose and Scope of Report

Firesafe Planning Solutions performed an assessment of risks related to wildfires in order to assess the intensity of a wildfire approaching the Project Site. This report provides the results of that assessment and objective hazard and risk assessments which can be used to establish the community risk reduction measures (hazard less reduction measures = risk) that are equal to or greater than the hazards which would be encountered in a worst-case scenario.

The study takes into consideration existing/future vegetative interface fuels, topography, fire , and weather conditions during extreme fire conditions. The report provides results of computer calculations that measured the fire intensity, flame lengths, rate of spread, and fire travel distance (arrival times) from worst-case scenario wildfires in both the extreme (Diablo wind) and the predominant (Onshore wind) wind conditions.

The Fire Hazard Planning Technical Advisory General Plan Technical Advice Series, 2022 Update Finalized – August 2022, Figure 7, Page 31, from the Governor’s Office of Planning and Research, provided a visualization of risk vs hazard for wildfires as shown in Figure 1. This report will use this guidance and terminology.

Figure 1 - Visualization of risk vs. hazard for wildfires-

The results of fire behavior calculations have been incorporated into the analysis of the interfaces of the project with adjacent wildlands and the potential ingress/egress routes used by the Project Site on a daily basis and under emergency conditions where evacuation might be possible.

Scope

This document will address the following tasks as outlined in the California Attorney General's "*Best Practices for Analyzing and Mitigating Wildfire Impacts of Development Projects Under the California Environmental Quality Act*" (AG Guidelines):

1. Determination if project impact will substantially impair an adopted emergency response plan or emergency evacuation plan.
2. Determine the project-specific Wildland Fire Hazard and Wildland Fire Risk to quantify issues that may exacerbate wildfire risks and thereby expose project occupants to pollutant concentrations from a wildfire or the uncontrolled spread of a wildfire;
3. Determine if the installation or maintenance of associated infrastructure (such as roads, fuel breaks, emergency water sources, power lines, or other utilities) may exacerbate fire risk or that may result in temporary or ongoing impacts to the environment;
4. Determine if people or structures will be exposed to significant risks due to the completion of the project; and
5. Consider whether a project will "expose people or structures, either directly or indirectly, to a significant risk of loss, injury or death involving wildland fires."

CEQA Appendix G,

Section XX. WILDFIRE. If located in or near state responsibility areas or lands classified as very high fire hazard severity zones, would the project:

- a. Substantially impair an adopted emergency response plan or emergency evacuation plan.
- b. Due to slope, prevailing winds, and other factors, exacerbate wildfire risks and thereby expose project occupants to pollutant concentrations from a wildfire or the uncontrolled spread of a wildfire?
- c. Require the installation or maintenance of associated infrastructure (such as roads, fuel breaks, emergency water sources, power lines or other utilities) that may exacerbate fire risk or that may result in temporary or ongoing impacts to the environment.

The AG guidelines encompass the CEQA Appendix G, Section XX, subsection a, b, and c requirements, and as this report addresses the AG guidelines, it addresses the Appendix G issues in the same effort. This report will not speak to the Appendix G requirements directly except as it applies to evacuation.

Project Description

The Project Site comprises approximately 2,341 acres located in the unincorporated area of the County of El Dorado (County) south of U.S. Highway 50 (US 50) and is located approximately 19 miles west of Placerville and 24 miles east of downtown Sacramento (Figure 2, Regional Location Map). This is where the 398-lot Marble Valley Master Plan was previously approved by the El Dorado County Board of Supervisors in 1998. If approved by the Board of Supervisors, the proposed VMVSP would replace the 1998 Master Plan approval. The site is approximately 1,000 feet southeast of US 50 and the Bass Lake Road interchange in El Dorado Hills, California (Figure 3, Project Location).

The Project Site is surrounded by the Cambridge Oaks residential development and US 50 to the north; Marble Ridge residential development and Valley View Specific Plan area to the west; Ryan Ranch residential development to the southwest; Sun Ridge Systems to the south; and Cameron Estates, the proposed Lime Rock Valley Specific Plan, Deer Creek Wastewater Treatment Plant, and Royal Equestrian Estates to the east.

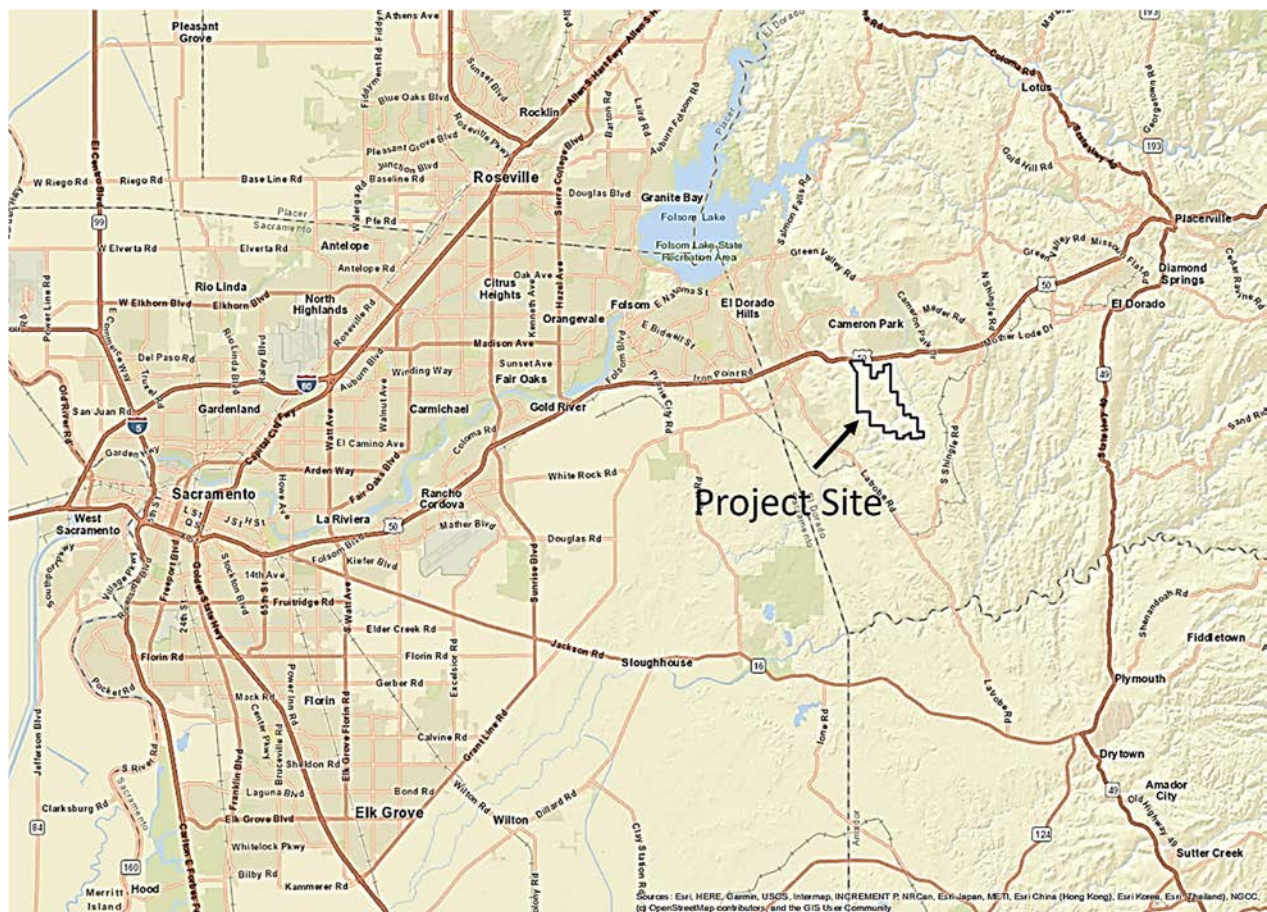

Figure 2 – Regional Location Map

The Project Site has two configurations under review for this analysis. The first is the project on its own; the second, is a configuration with an adjoining project (Lime Rock) to the east which will share some infrastructure (roads and evacuation points) with the Project Site (Figure 3).

The Project Site is proposed with up to 3,236 dwelling units, 475,000 square feet of commercial use, 87 acres of public facilities/recreational use, 1,282 acres of open space, 42 acres of agricultural use, and 73 acres of new road impact areas and future right-of-way. Planned improvements will take place on approximately 1,875 acres located mostly north of Deer Creek. The proposed project is designed in a manner that concentrates a majority of the development (clustered development) along a 1-mile core adjacent to the entry roadway and preserves, enhances, and highlights the historic character of the site derived from the historical use of the property for limestone mining.

Figure 3 – Vicinity Map

Current Environmental Conditions

General Location of Site and Adjacent Wildland

The Project Site will have undeveloped natural areas on all sides of the majority of the development area rather than directly abutting existing development. The site was designed with the “clustered development” concept, where density is concentrated in the development area to maximize the amount of open space on the balance of the site. This is illustrated in Figure 4.

The majority of the unclassified (no dominant lifeform – light red) is in the existing development areas. The grasses are indicated in light yellow, the shrubs in dark brown, and the green and

light blue areas are trees. The dark blue (non-vegetated) areas are water bodies or quarries for the most part.

Figure 4 – Land Use Map

Landfire data is provided in 30-meter grids with the predominant value in the grid representing the entire grid. This is true for all of the data sourced from the Landfire site (elevation, slope, aspect, wildland fuels, existing vegetation type, canopy coverage, etc.). It is necessary to review the data to ensure that processing errors have not occurred, which has been done at a macro level.

The wildland interface is a mixture of Herbaceous (grasses) and Shrublands (chaparral/brush) and conifer/oak woodlands. Much of this open space will be native species with the exception of the fuel modification/defensible space zones. Fire behavior modeling was completed using the data from the Landfire data site (<https://www.landfire.gov>) which provided the source for the fuels types, vegetation type, slope, aspect, and elevation for this report and for the models used in this report. Figure 5 provides an illustration of the various wildland fuel types (grasslands, shrublands, tree covered/canopy (open or sparse), sparsely vegetated, no dominant vegetation) in general categories. For the most part, this illustration is simply grass, shrub, trees, little vegetation or areas where the diversity of vegetation does not allow for classification under this category.

When the development area is added (Figure 6), it is possible to see the interface that will be created with this project. Figure 7, on the following page, provides the development area for the alternative development configuration (Lime Rock Project) to illustrate the east interface if that development occurs as currently envisioned. A large amount of the shrub interface is eliminated or modified, reducing the wildland threat in that area.

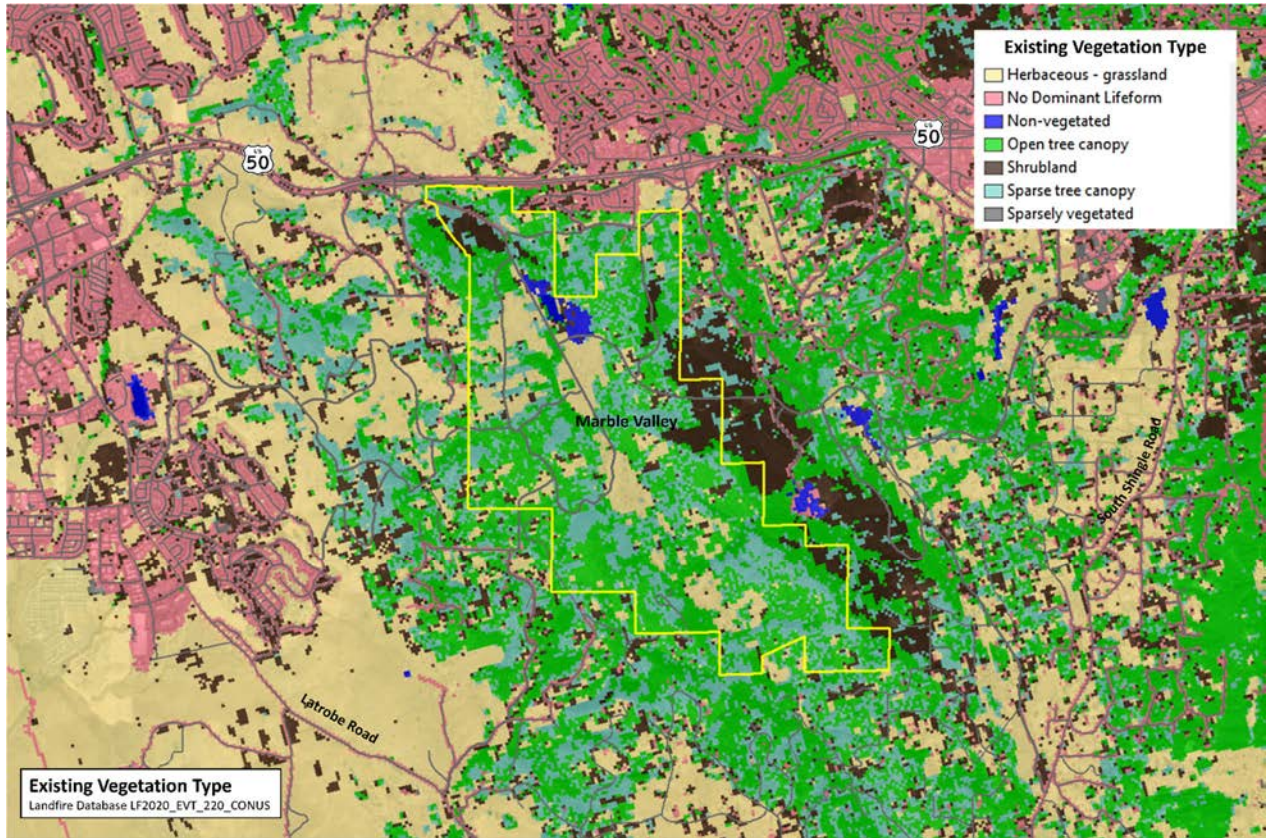

Figure 5 – Vegetation Type Map

Agency responsible for fire protection

The El Dorado Hills Fire Department (EDHFD) is the service provider to the Project Site on the west side of the Project Site and El Dorado County Fire Protection District (EDCFPD) is the current service provider to the east side of the Project Site as shown in Figure 8.

As shown in Figure 9, the entire Project Site is in SRA. All, or nearly all, of the SRA lands, are in one of the three Fire Hazard Severity Zones classifications. (Very High, High, or Moderate).

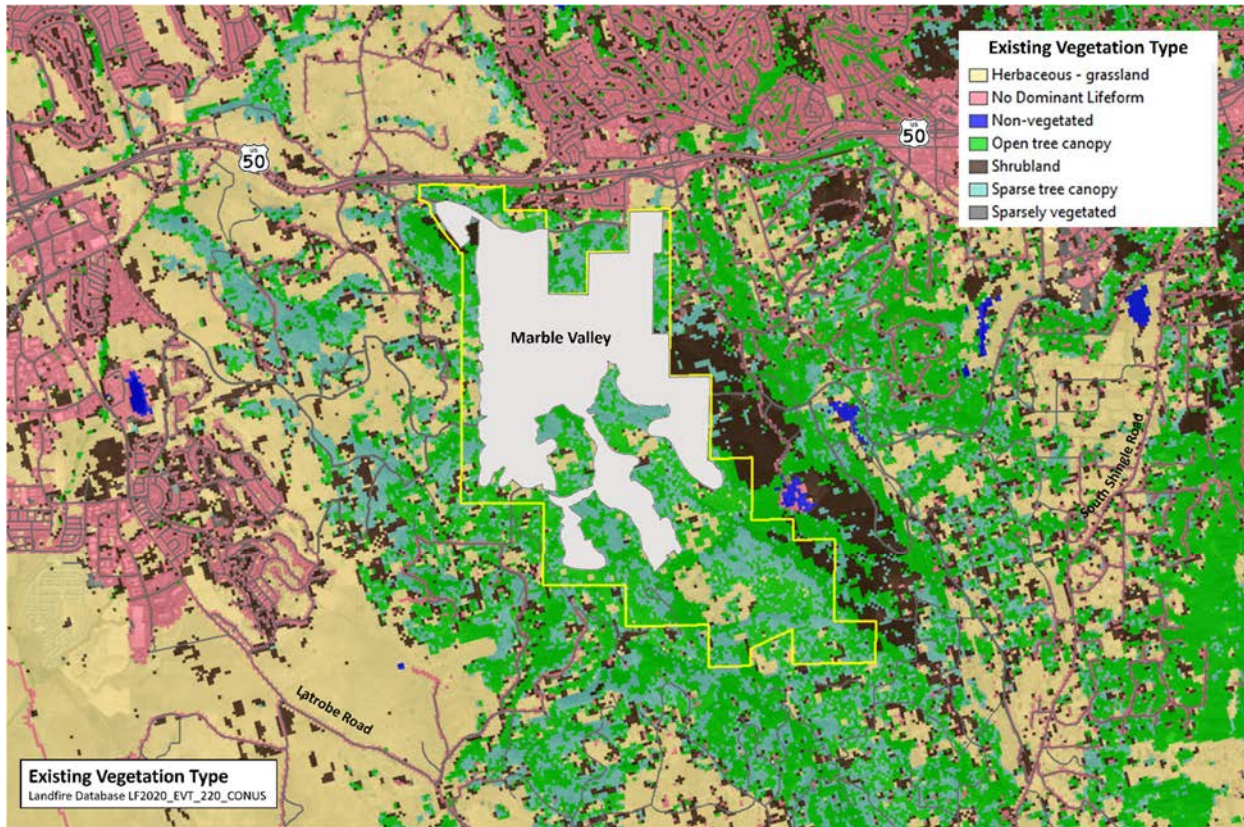

Figure 6 – Vegetation Type Map with Development Area for Marble Valley

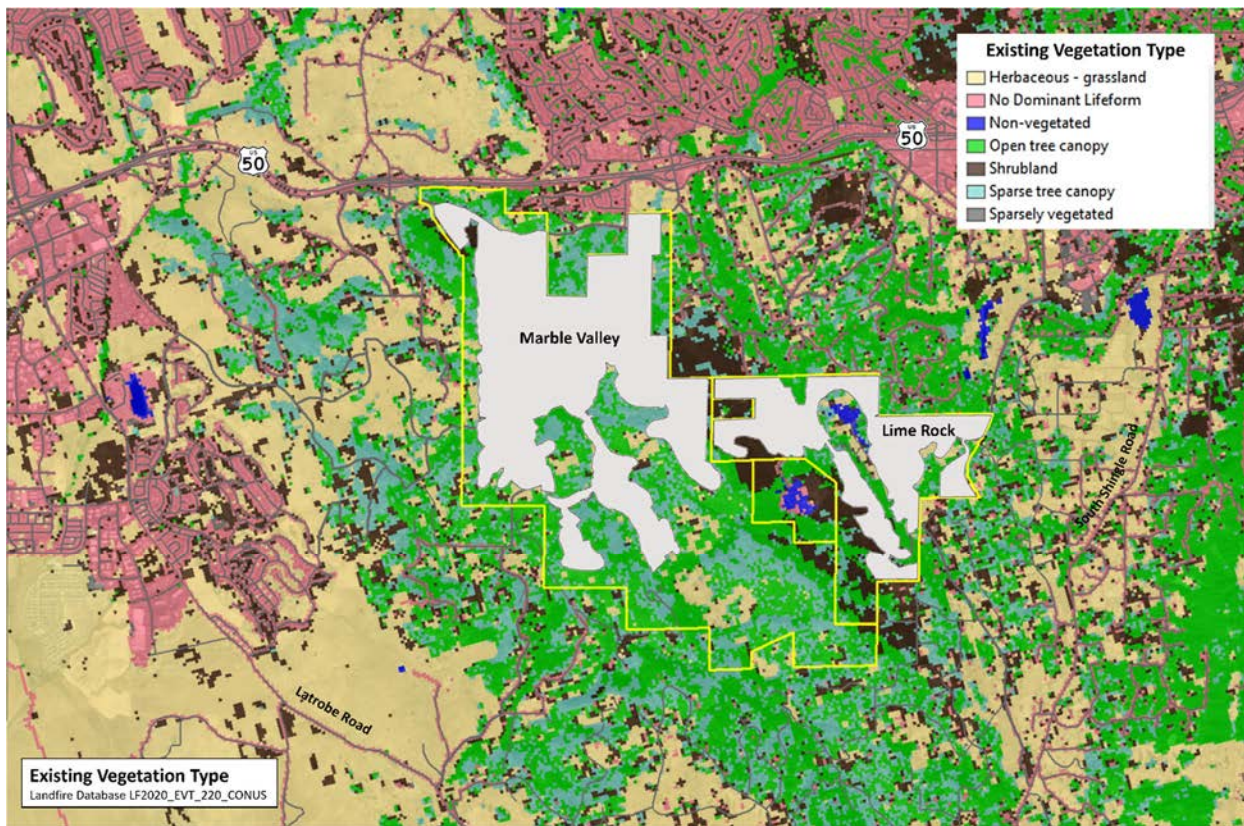

Figure 7 – Vegetation Type Map with Marble Valley and Lime Rock Development Areas

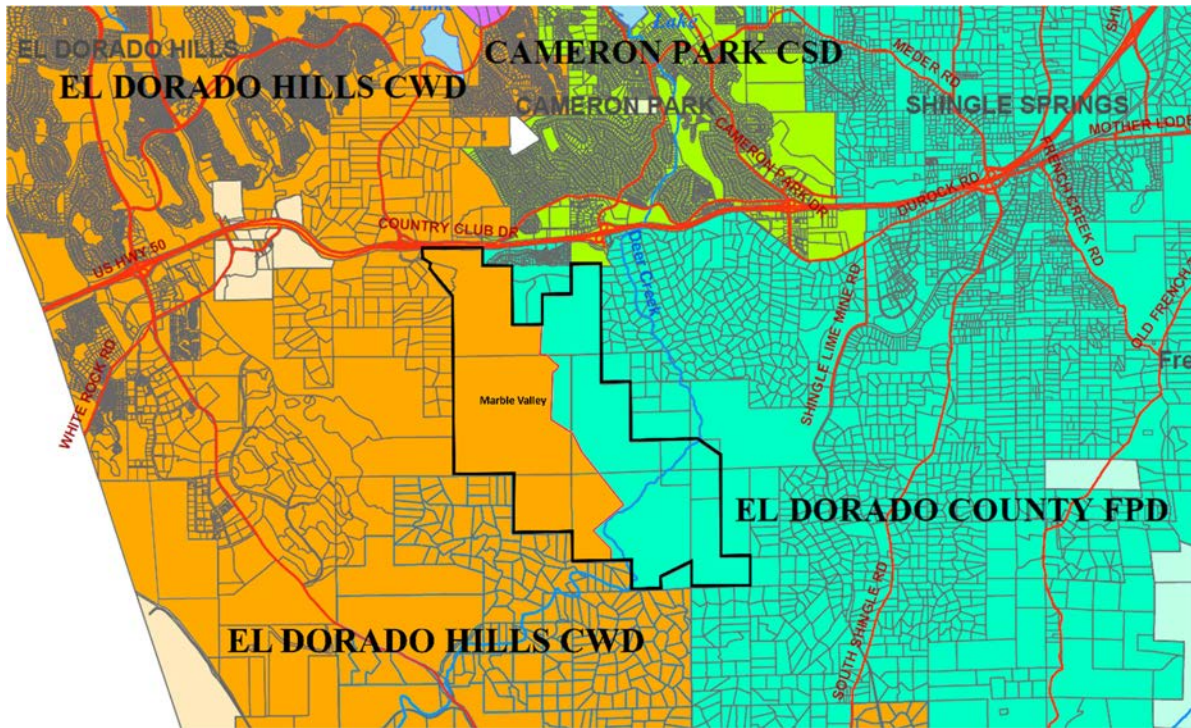

Figure 8 – Fire Protection Area Boundaries

SRA/LRA/FRA

Figure 9 – Map Responsibility Areas (SRA/LRA/FRA)

Fire Severity Zones and proximity

Fire Hazard Severity Zones are currently based on potential fuels, fire weather conditions, and terrain and represent potential fire hazard exposure to structures and other human infrastructure assets. FHSZ areas are adopted as a Title 14 regulation, fulfill the obligations laid out in Public Resources Code (PRC) Sections 4201-04, and are essential in various fire safety regulations, building construction standards, and real estate hazard disclosure requirements. These zones were determined in November 2007 for SRA and September 2008 for LRA and are currently in the process of being revised by CalFire (CalFire Website). The 2007 Fire Severity Zone Map is provided in the Reference section of this report. New “draft” maps are out for review for the SRA areas for the entire state. In Figure 10, are the proposed classification for the Protect Site and adjoining lands. These new maps will be adopted within the next few months. The map shown in Figure 10 is the configuration which is being recommended for adoption.

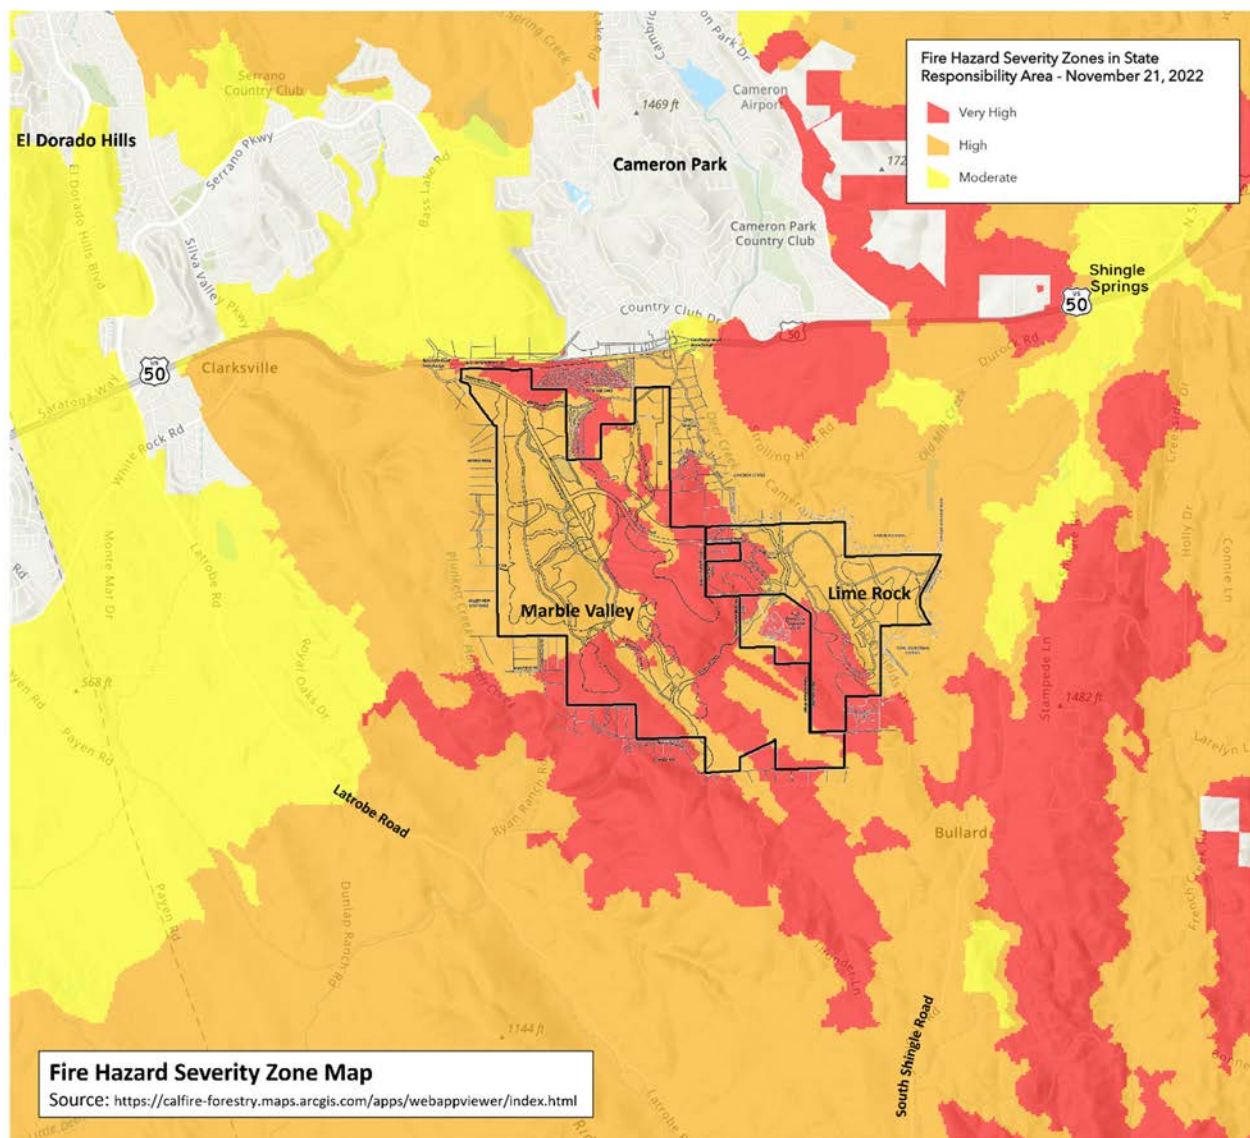

Figure 10 – Fire Hazard Severity Zones (2022)

Wildland Interface/Intermix

The wildland-urban interface (WUI) is defined by the U.S. Forest Service as any area where “humans and their development meet or intermix with wildland fuel.” This area includes communities that are within a half-mile of this interface. The WUI is classified into two categories:

1. Interface WUI — where structures are adjacent to the wildland vegetation. A clear line of delineation is provided.

Interface

2. Intermix WUI — where structures intermingle with wildland vegetation. Each structure or group of structures has its own interface.

Intermix

Figure 11 – Interface vs. Intermix

Source: “Fire FAQs-Are Structures Fuel? The Wildland Urban Interface and the ‘Built’ Environment”, Daniel Leavell, Stephen A. Fitzgerald, Carrie Berger, Gavin Horn, EM 9291 Published August 2020

The Project Site will utilize a WUI Interface for each of the planning areas. Some native areas will remain between planning areas, but most of the development will create areas where the only interface with native fuels will be on the perimeter. Figure 4 illustrates the project’s WUI interface. This is discussed in more detail in the analysis of the fire behavior.

Codes, guidelines, and standards

The Project Site will be required to provide protection measures as required by a number of Laws, Codes, Ordinances, Regulations, Guidelines, and Standards (collectively, Regulations). Most of the Regulations apply to all areas of the Project Site. Below are the major Regulations that will impact the Project Site:

- PRC Sections 4290 through 4299.
- PRC Sections 4201 through 4204 for State Responsibility.
- Title 14 of the California Code of Regulations (14 CCR), Division 1.5, Chapter 7, Subchapter 2, Articles 1-5, “State Minimum Fire Safe Regulations.”
- California Code of Regulations, Title 24, Part 9, California Fire Code, Chapter 49.

- California Code of Regulations, Title 24, Part 2 (Volumes 1 and 2), California Building Code, Chapter 7A.
- California Code of Regulations, Title 24, Part 2.5, California Residential Code, Section R337.
- Fire Code of the El Dorado Hills County Water District (California State Fire Code as amended and adopted)
 - Section 4906 – Vegetation Management
 - Section 4907 – Defensible Space
- El Dorado County Vegetation Management and Defensible Space Ordinance #5101,
- El Dorado Hills Fire Department, Fire Protection Standards will apply to the west side of the project.
- El Dorado County Regional Fire Protection Standards apply to the entire site (adopted into the EDHFD standards)

As further described below, the Project Site will have wildland-specific requirements before, during and after construction.

Prior to Construction

The Project Site will be required to have an approved Fire Safe Plan concurrent with the submission of any small lot subdivision of land that would result in five (5) or more parcels within the EDHFD responsibility areas (Specific Plan Policy 6.47 provides for the Fire Safe Plan at the Tentative Map submittal). A Fire Safe Plans shall be based on a site-specific wildfire risk assessment that includes considerations of the location, topography, aspect, flammable vegetation, climatic conditions, and fire history. The plan addresses water supply, emergency vehicle access, building ignition and fire-resistance factors, fire protection systems equipment, defensible space, fuel breaks, buffer zones and vegetation management to reduce hazard severity and risk. The Fire Safe Plan summarizes all fire related recommendations for the project, the timing in which the recommendations are to be implemented, and who the responsible party is to complete these recommendations.

Additionally, El Dorado Hills Fire Department Standard W-002 (Dated 6-6-22) requires that prior to the recording of a Parcel Map or approval of a Final Subdivision Map, or other entitlement for projects described in Section IV by the County of El Dorado, the project shall adequately demonstrate that all provisions of the Fire Safe Plan, including the maintenance of green belts, greenways, fuel breaks, shaded fuel breaks, and other vegetation management requirements, have either:

[1] been met to the satisfaction of the AHJ (Authority Having Jurisdiction) and CAL FIRE; or

[2] that a development agreement or bonding of the required infrastructure has been agreed to by the AHJ and CAL FIRE.

Areas within the EDCFPD will also be a part of the Fire Safe Plan per the Specific Plan Policies.

The Project Site Specific Plan requires the development process to abide by a number of policy decisions, some of which are provided below for this project:

C.17 Public Services (Fire Protection)

Policy 7.25

The local fire protection district shall review and approve all discretionary applications for tentative subdivision maps, parcel maps, and planned development permits prior to County approval to ensure the adequacy of emergency water supply, storage, conveyance facilities, and access for fire protection. Recommendations may be incorporated as conditions of approval.

Policy 7.26

After the adoption of the Specific Plan and prior to the submittal of the first small lot tentative subdivision map, the Project Proponent will prepare a Wildfire Safety Plan (WSP). The California Department of Forestry and Fire Protection and the applicable local fire protection district (El Dorado Hills County Water District or the County Fire Protection District) will review and approve the WSP prior to the approval of the first small lot tentative subdivision map.

Policy 7.27

Pay all applicable fire impact fees at building permit issuance and/or participate in any applicable Mello Roos districts required to fund public facilities as specified in the PFFP.

As indicated, the Wildfire Safety Plan (Fire Safe Plan) will be completed for review prior to the first small lot tentative subdivision map submittal and must be approved by CalFire and the applicable local fire district prior to the approval of that first small lot tentative subdivision map.

- The plan evaluates whether the project will substantially impair an adopted emergency response plan or emergency evacuation plan.
- The plan identifies potential mitigation measures that can be adequately employed to reduce the impacts caused to the existing response or evacuation plan.
- The plan evaluates whether the project exacerbates the wildfire risk due to slope, prevailing winds and other factors.
- The plan identifies potential mitigation measures that can be adequately employed to reduce the overall wildfire risk due to the factors identified.
- The plan identifies the installation or maintenance of associated infrastructure (such as roads, fuel breaks, emergency water sources, power lines or other utilities) that may exacerbate fire risk or that may result in temporary or on-going impacts to the environment.

- The plan identifies potential mitigation measures for vegetation reduction around emergency access, evacuation routes and associated infrastructure that can be implemented to ensure that this infrastructure is installed and maintained by the project and successor parties.
- The plan identifies whether the project will expose people or structures to significant risks, including downslope or downstream flooding or landscape, as a result of runoff, post-fire slope instability, or drainage changes.
- The plan evaluates the local fire protection capabilities; and fire suppression water supply capabilities to necessary to adequately serve the project and makes recommendations to improve or mitigate deficiencies identified during the analysis of the project.
- The plan evaluates community wildfire evacuation routes required for the project for their capacity, safety, and viability under a range of scenarios and to ensure consistency with CAL FIRE, CAL OES and AHJ requirements.
- The plan provides legally binding statements regarding community responsibility for the maintenance of fuel modification zones. The legally binding statements is required to be incorporated into the project covenants, conditions, and restriction regarding property owner responsibilities for vegetation maintenance.

Protection During Construction

Both fire agencies (EDHFD and EDCFPD) have adopted Chapter 33 of the California State Fire Code entitled Fire Safety During Construction and Demolition with amendments. This section of the Fire Code provides requirements for “Precautions Against Fire”, Combustible and Flammable Liquids, Flammable Gases and Explosive. Additionally, it requires readily accessible means of reporting emergencies, access roadways and fire department water supply to all areas where combustible construction is occurring.

This section (CFC Chapter 33) requires the development, implementation, and maintenance of an approved, written Site Safety Plan establishing a fire prevention program at the Project Site applicable throughout all phases of the construction, repair, alteration, or demolition work. This plan addresses the requirements of the Fire Code, the duties of staff, and staff training requirements. The Site Safety Plan must be submitted and approved before the issuance of a building permit. Any changes to the plan must be submitted and approved by the fire department.

Prior to the approval of a certificate of occupancy for a building, the project shall demonstrate to the satisfaction of the AHJ and CAL FIRE that the project complies with all applicable provisions found in the Fire Safe Plan.

Protection After Construction

The Project Site is within a Fire Hazard Severity Zone, which requires the enforcement of Fire Chapter 49. This chapter provides for increased wildfire building construction protection (maintenance, additions, and remodels must be in compliance with wildland standards), vegetation management, defensible space, and compliance with an Approved Fire Protection Plan. These requirements provide for the implementation and maintenance of California Building Code Chapter 7A, California Residential Code Section R337, and Californian Reference Standards Code Chapter 12-7A. It further requires that buildings and structures be

maintained in accordance with California Public Resources Code Section 4291, California Code of Regulations, Title 14, Division 1.5, Chapter 7, Subchapter 3, Article 3, Section 1299.03; California Government Code Section 51182 and California Code of Regulation, Title 19, Division 1, Chapter 7, Subchapter 1, Section 3.07. The Project Site is also within the SRA, which requires it to comply with the SRA Fire Safe Development Regulation as specified in Title 14, Division 1.5, Chapter 7, Subchapter 2. The Project Site will need to be maintained to the same standards and Regulations that were applicable at the time of construction on an ongoing basis.

Additionally Standard W-002 requires that prior to June 1st of each year the property owner or their representative shall demonstrate to the satisfaction of the AHJ and CAL FIRE that the project:

[1] complies with all relevant provisions of the Fire Safe Plan; and

[2] that all fire hazards in the development have been mitigated.

This standard further requires that the Fire Safe Plan be reviewed and updated by the property owner (Home Owners Association or HOA for common areas) no less than once every five calendar years after its original approval to ensure that the project complies with all current regulations and requirements for existing developments. The AHJ and CAL FIRE shall review and approve this plan update prior to its use. The AHJ is responsible for routine inspections of all of the installed fire protection features (including fuel modification and defensible space).

In accordance with AB38 Inspections (California Civil Code §§ 1102.6f and 1102.19) properties must be inspected by the local fire agency during the escrow process when property changes hands. Compliance can be deferred for up to one year, with the responsibility shifting to the new owner if agreed to by both parties.

Public Information and Resident Education

All of the requirements for the fuel modification/defensible space zones, defensible space requirements, limitations on remodels/additions on the interface lots, and community planting restrictions will be included in the disclosure documents provided to the owners during the escrow process. Additionally, these requirements will be fully detailed in the Project Site CCR's (Covenants, Conditions, and Restrictions) legal documents that are filed with the county recorder's office and made a part of the official real estate records that run with the land that is part of the community. The HOA will have the responsibility to inform the residents of the requirements, review and approve changes to the property and provide a process to ensure compliance with the community standards where applicable. The CCR's will be reviewed and approved by various governmental agencies (El Dorado Hills Fire, El Dorado County Fire, CalFire, and the County of El Dorado) in the development process.

Large fires in the area are due to several issues. Access and topography are part of it. Roads in the lands to the east, west, and south of the Project Site have limited access to the areas where these fires can burn. The topography can be steep, and most of it is well-vegetated. The general area does not have a large number of fire stations which can arrive quickly in the early stages, and fires that occur are generally related to the transportation and infrastructure (powerlines and roads) in the area that provide the ignition sources in many cases. This area sometimes experiences thunderstorms/lightning which produce strong winds and ignitions without the rainfall necessary to put out the spot fires. All of these factors are covered in more detail later in this report.

Weather

The weather has a significant impact on the ability of a small fire to become a large fire. Within the weather category, wind, relative humidity, temperature, and interaction with the topography are especially impactful.

High temperature, low humidity, and wind combine to create “Fire Weather”. In the general area of the Project Site, the regional weather has a strong history of extreme Fire Weather. Conditions like these are common to the point where the National Weather Service has a specific system used to identify when extreme conditions are being achieved, and additional action should be taken. On its website, CalFire describes as follows:

The National Weather Service issues Red Flag Warnings & Fire Weather Watches to alert fire departments of the onset, or possible onset, of critical weather and dry conditions that could lead to rapid or dramatic increases in wildfire activity.

A Red Flag Warning is issued for weather events which may result in extreme fire behavior that will occur within 24 hours. A Fire Weather Watch is issued when weather conditions could exist in the next 12-72 hours. A Red Flag Warning is the highest alert. During these times extreme caution is urged by all residents because a simple spark can cause a major wildfire. A Fire Weather Watch is one level below a warning, but fire danger is still high. [Red Flag Warnings & Fire Weather Watches \(ca.gov\)](https://www.fire.ca.gov/red-flag-warnings-and-fire-weather-watches)

Extreme Fire Behavior is a term used by the National Wildfire Coordinating Group (NWCG) for conditions which imply a level of fire behavior characteristics that ordinarily precludes methods of direct control action. One or more of the following is usually involved: high rate of spread, prolific crowning and/or spotting, presence of fire whirls, and strong convection column. Predictability is difficult because such fires often exercise some degree of influence on their environment and behave erratically, sometimes dangerously.

Temperature

The temperature in and of itself does not have a large impact on fire behavior but the effects of temperature on other factors such as Relative Humidity make temperature important to the fire behavior discussion. More direct sunlight increases fuel temperatures and decreases the amount of heat needed to raise the fuel to its ignition temperature, but since most wildland fuels must be

raised to over 400°F to sustain combustion, the difference of 10 or 20 degrees in the atmospheric temperature has limited direct effect.

Relative Humidity

Relative humidity (RH) indicates how much moisture is in the air. Expressed as a percentage, it provides an objective measurement of the amount of water vapor that is in the air compared to the amount needed to be saturated (100% RH). When RH is low, moisture can be removed from the vegetation at a high rate creating drier vegetation conditions that burn easily and at a faster rate. Fuels (wildland) are categorized by the amount of time (time lag) it takes them to adjust the plant moisture level to the atmospheric level (63% of the difference) in one-hour, ten-hour, hundred-hour, and thousand-hour fuels. One- and ten-hour fuels have the most impact on the flaming front (active burning) of wildland fires in grass/brush fuels. For example, a grass fuel (one-hour) could be at a very high level of fuel moisture (90%) due to overnight fog. When the sun comes up, and the fog burns off or a dry air mass moves into the area, if the RH were to drop to 20, then in the first hour, the fuel moisture would move from 90% to 45% (63% of the difference between 90% moisture in the fuel and 20% moisture in the air) in the first hour and down to 30% by the end of the second hour and 24% by the end of the third hour. Each time moving 63% of the difference between the fuel moisture and the air moisture.

Humidity varies with temperature (generally, when temperature increases, humidity decreases, and vice versa). Humidity is important because it affects fuel moisture content and therefore, the fuel's combustibility. This is the reason that hot, dry Santa Ana wind conditions tend to create Fire Weather and increase the level of risk as they continue to impact the fuels for several days, weeks, or months in the dry season for southern California. Hot, dry, and windy are a bad combination.

Wind

The wind is the most obvious factor in creating Extreme Fire Behavior. While Extreme Fire Behavior is possible without extreme wind, such as fuel-driven, plume-dominated wildfire, they are often found together. The Station Fire in southern California in 2009, was a prime example of fuel and low relative humidity-driven fire, with much of the fire growth occurring in the absence of significant winds ([The Station Fire: An Example of a Large Wildfire in the Absence of Significant Winds \(weather.gov\)](#)). This was not what is normally seen in the recent history of fires in California, but prolonged drought, bug kill and other factors which are increasing the amount of dead fuels in the wildlands are making these types of fires more common than they were in recent history. The wind is normally one of the prime factors. The reason for this is that, in fine fuels like grasses, wind can accelerate the fire to the maximum flame length and Rate of Spread (ROS) with little wind compared to the wind speeds that are possible under fire weather conditions.

One method of illustrating this fact is to show grass wildland fuels (dry climate) at various wind speeds and look for the point at which the fire from a specific fuel reaches its maximum energy output (all fuel consumed; no additional fuel to burn). Using the BehavePlus software from the U.S. Forest Service to complete the comparison, an extreme moisture scenario was used (3% for one-hour fuels, 4% for ten-hour fuels, 5% for 100-hour fuels, 30% for live herbaceous fuels and 50% for live woody fuels) for the fuel moisture levels in the time lag dead and live fuels. Three

dry climate grass fuels were used (GR1, GR2, GR4), which are the fuels normally found in most of California for grasses. The results (Figure 13) indicate that the GR1 fuel reaches the maximum flame length and ROS at 5 mph (midflame wind speed), while the GR2 fuel reaches maximums at 13 mph and the GR4 at 25 mph. For this example, the 20-foot winds are two times the midflame wind speed. 20-foot winds are defined as sustained winds averaged over a 10-minute period and measured 20 feet above the average height of nearby vegetation. (This is the standard reported by the Remote Automated Weather Stations (RAWS) owned by land management agencies and used in the National Fire Danger Rating System (NFDRS)). Using the 20-foot winds at two times the midflame wind speed allows for the perspective of how little wind is needed on a flat plain. When the slope is added, the GR1 is at maximum without wind, the GR2 drops to 9 mph and the GR4 drops to 22 mph. Figure 13 provides the output from the Behave modeling for this example.

The regional area around the Project Site has one Remote Access Weather Station or RAWS

(BENC1) which is monitored/ maintained by a governmental agency to measure, record, and transmit Fire Weather data on a routine basis over extended periods of time. Most of these RAWS sites have been in place for many years, if not decades. These sites are good for establishing the long-term wind (speed, direction, and gusts), temperature, and RH.

Figure 14 – Location map for location weather collection sites

The Ben Bolt RAWS is located to the southeast of the Project Site. The RAWS is approximately 2.75 miles to the SE from the southern boundary of the Project Site. The location for Ben Bolt is provided in Figure 14, as well as four additional weather data locations around the Project Site, two of which are weather stations maintained and monitored by Pacific Gas and Electric (PGE) as part of the company’s Wildland Fire Safety program and two private weather stations which are part of the Citizen Weather Observing Program (CWOP) sponsored by the National Weather Service. The company (PGE) uses data to make decisions on Public Safety Power Shutoff (PSPS) actions. The data is available to safety personnel and the general public in nearly “real-time.” Most of these PGE sites are mounted on utility poles owned by the company.

The RAWS site data has over 20 years of recent data, while the PGE sites have all come online within the past 4 years, and some in the area have been installed in the past year (those have not been used here). The data from the RAWS sites shows a consistent pattern of winds from the south to west and from the north to northeast, with the stronger winds originating from the S/SW (Figure 15). The data tables for the RAWS site are in Figure 16.

The data summaries in Figure 16 are derived from over 179,000 data points over 20+ years, with maximum/minimum summaries encapsulating the data for recordation by the hour. The green highlighted areas of the summary show the flow toward the mountains, and the light red the flow from the mountains into the central valley. The two highest wind measurements occurred from the S and SE, but the predominant flow is from the N to NE (34.5% of the time) and S to WSW (34.9% of the time). It should be noted that only 182 hourly reports out of 179,528 (0.101%) have wind gust speed that exceeds 40 mph. Wind gusts exceeding 30 mph do not amount to 1% of the wind data observations. The 99th percentile for wind gusts in this data base is 27 mph.

Figure 16 – Ben Bolt RAWS Data Summary

Four additional weather data collection points have been used around the Project Site. The two PGE sites (PG663 and PG357) have databases for the past 2.5+ years, with both going into service in the spring of 2020. Each has about 130,000 data points. These sites have direct readings every six minutes (10 times per hour), whereas the RAWS had hourly summaries. The lowest/highest values are not any different, but the depth of the data is greater with respect to the wind direction and duration of a particular data value.

PGE monitors the weather sites 24/7 in an effort to provide data for planning and protecting communities from wildfires and assist in the prediction of fire-prone weather and assist in the prevention of wildfires where possible. One method they use is the Public Safety Power Shutoff (PSPS) forecast and implementation program. This is designed to reduce or eliminate possible wildfire sources from the electric grid during times of high risk.

Access to PGE’s interactive weather and fire-detection satellite maps allows local fire officials and the general public the ability to review the weather in the local area so that they can be better prepared. This same data provides a historical view of past fire-prone weather which is very useful to the assessment of future risk. Data from the two sites is provided in Figure 17.

Figure 17 – PGE Sites Weather Data

Data from the PGE sites is more localized and provides a view at a more micro level than the RAWS site. The wind directions, wind speeds, relative humidity, and temperatures are similar and within the overall parameters of the RAWS dataset extremes.

The last two sites are private weather stations that are a part of the CWOP. CWOP runs data checking and analysis on its site to increase the quality of the data. These sites (E8856 and F5459) are located 2.71 miles to the NNW (F5459) and 1.38 miles to the SSE (E8856) of the Project Site boundary. The data from these sites are within the expected values but it should be noted that in these datasets, over 40% of the values are “null” (missing or blank).

These databases, used as a primary source, would be suspect due to the null values, but as an accessory source, utilized to find data outside of the primary site data, they have value. Both sites have data beyond the PGE data windows. F5459 has 175,791 data points over a 3.42-year period (5/19 to 10/22). E8856 has 675,262 datapoints over a 6.6-year period (3/16 to 10/22). Even with the null values, the amount of data present is significant. The data summaries are provided in Figure 18.

Figure 18 – CWOP Sites weather data

From a fire modeling perspective, wind (speed and direction), relative humidity, and temperature, (to a lesser degree) are important elements. These output factors are combined for all the weather sites in Figure 19. The maximum values (minimum for RH) are provided along with the values for the 3rd and 99th percentile of the dataset. The RAWS site has the max/min values for all of the datasets. Modeling assumptions have been derived from this data. The maximum wind value is a 64-mph wind gust, the highest temperature was 117 degrees F., the lowest RH was 3%, and the predominant direction is from the N to NE (34.5% of the time) and S to WSW (34.9% of the time).

For this report, the minimum fuel moisture for 1-hr fuels will be 3% based on the RH values shown in Figure 19, as found at the referenced site. Wind assumptions, based on the values in Figure 19, will be modeled at sixteen locations with one or more wind directions from:

SW at 65/50/40/30	ENE at 50

Figure 19 - Weather Data Summaries for All locations

Intensity

The intensity of a wildfire is measured in the energy release expected from the flaming front of the fire (active burning). Intensity is greatly affected by topography, weather, and the amount of fuel available to burn. For example, a brush fire in heavy chaparral in a steep canyon can produce a greater wildfire intensity than short grass fuels on flat ground. Wildfire intensity is measured in units of heat transfer per length of the fire edge within the fire modeling community but is more often expressed in terms of flame length for easier understanding in training and discussion with those who fight fires and those who must live with the potential of wildland fires.

Fire intensity is the primary wildfire characteristic related to potential fire effects. Typically, the greater the intensity, the greater the loss, but this is not always the case. (USDA Forest Service Gen. Tech. Rep. RMRS-GTR-315. 2013, page 5)

The factors affecting wildfire intensity include the elements of the fire behavior triangle (fuel, weather, and topography) as well as spread direction (heading, flanking, backing, etc.). At a basic level, wildfire intensity can be assessed for a point, stand, or landscape without consideration of fire spread by assuming that a fire occurs at the given location(s) under specific weather, fuel moisture, and fire spread parameters (heading, flanking, or backing). Typically, this is assessed as

the near-maximum potential (for example, heading fire under 97th percentile fuel moisture and wind conditions).

There may be a very low probability of a wildfire occurring under these conditions in any particular area, but nevertheless, this level of assessment provides useful information about the potential wildfire behavior that different areas of a landscape are capable of producing. At the landscape scale, this type of wildfire hazard assessment may also be used to identify where on a landscape there is the potential to meet or exceed specific wildfire behavior thresholds, thus aiding the identification and prioritization of management opportunities. (USDA Forest Service Gen. Tech. Rep. RMRS-GTR-315. 2013, pages 7-8)

In order to assess potential intensity, it is necessary to examine the fuels, topography, and configuration in order to accurately assess both the hazard and the risk to the adjacent areas. The topography includes elevation, slope, aspect, and features, such as canyons, valleys, or rivers.

Fuels (wildland and built)

Wildland fuels on and near the Project Site consist mainly of grass, shrubs, and open canopy treed vegetation cover as indicated in Figure 5. Figure 20 provides an illustration of the wildland fuels on and near the Project Site. The fuels are classified by number in categories as listed in the legend.

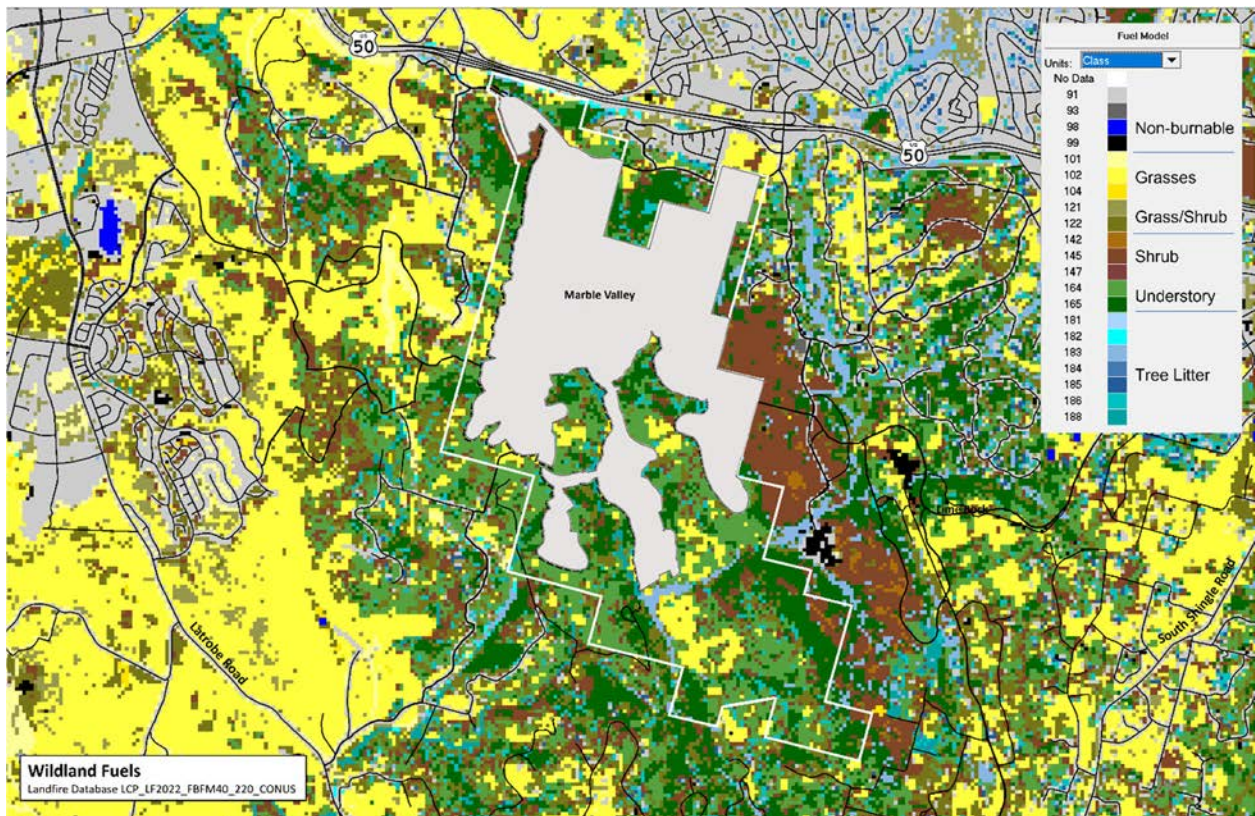

Figure 20 – Wildland Fuels Map

In each category, the amount of fuel is generally greater as the number increases. Grass fuel 101 has less combustible fuel available than grass fuel 102. The 100's are grasses, the 120's are grass/shrub mixtures, the 140's are shrub fuels, the 160's are understory fuels, and the 180's are tree litter fuels. These all apply to surface fuels (within 6' of the ground), as canopy fuels are dealt with separately in other modeling modules. The Project Site (shown here with the Marble Valley development area shaded) is mostly grass and grass/shrub fuels with some areas of shrub-only fuel. Canopy fuels are not predominant. Fuels are assessed in 30-meter grids, with the predominant fuel type within the grid representing the entire grid.

The Marble Valley Project Site consists of a valley approximately two miles wide (east to west) by four miles long (north to south). Elevations on-site range from approximately 700 to 1,200 feet above mean sea level. Marble Creek flows from north to south through the valley and joins Deer Creek near the southern boundary. Deer Creek flows from the northeast to the southwest along the southern boundary.

There are extensive blue oak woodlands and savannahs throughout the valley, and riparian woodlands are found along much of Marble and Deer Creeks (Figure 21 – Vegetation Communities with Development Overlay). Patches of white-leaf manzanita chaparral and annual grassland are also present on-site. The steep terrain is drained by intermittent and ephemeral drainages and seasonal wetland swales. Other aquatic features on the property include seasonal wetlands, seasonal wetland swales, seeps, two quarry ponds, and stock ponds. Rural residences surround the Project. (2012-020 Bio Resources/SS Plant Surveys/ Report/SS Plant Survey Report 3.28.13)

Per the Bio Resources report for the Project Site, large stands of white-leaf manzanita chaparral are present in the northern and eastern portions of the Project site. The chaparral vegetation community is dominated by white-leaf manzanita (*Arctostaphylos viscida*) and chamise (*Adenostoma fasciculatum*). Other shrubs frequently occurring in the chaparral include buckbrush (*Ceanothus cuneatus*), toyon, coyote brush (*Baccharis pilularis*), western red bud (*Cercis occidentalis*), and yerba santa (*Eriodictyon californicum*). The current shrub component of this chaparral is dense, and as such, very few plants are present in the understory. There are, however, large openings in this community that support plant species typical of the annual grassland vegetation community. (2012-020 Bio Resources/SS Plant Surveys/ Report/SS Plant Survey Report 3.28.13)

These findings from the biologist report are in concurrence with wildland fuels found in the Landfire database used for the fire modeling in this report. The majority of the future wildland interface will be woodlands with the exception of the remaining chaparral areas to the east of the Project Site in an undeveloped parcel (some of which is within the Lime Rock development area). The bio report validates the Landfire data at a macro level.

Photos of site wildland fuels are provided on the following pages in Photo 1 through Photo 4. In Appendix A, site photos for all areas are provided.

Photo 2 – Open Canopy Understory Fuels

Photo 3 – Grassland Fuels

Photo 4 – Wildland Tree Litter Fuels

Slope

Slope can influence how a fire will move up or down hills. A fire that ignites at the bottom of a steep slope will spread much more quickly upwards because it can pre-heat the upcoming fuels with rising hot air. The upward drafts are more likely to create spot-fire conditions. In the absence of winds, fires usually move faster uphill than downhill, so the steeper the slope, the faster a fire moves. Wind can overpower the slope factor, but generally, steeper slopes result in more extreme fire behavior. If the slope is below a site, it will have a more significant impact on the site than if the slope is moving up and away from the site.

Slope can be measured in degrees or percentages. A 45-degree angle is a 100% slope because it rises one foot for each linear foot of the slope. Figure 22 provides an illustration of the slopes around the Project Site prior to grading. The slope percentages shown in the graphic are averaged for the 30-meter grid that is displayed for that area. In the graphic one of the possible configurations is provided for reference. The slopes within the development area will be changed during the grading process and, for the most part, will be reduced in steepness or averaged over a larger area. For the purposes of this report, the portions of land in the native interfaces where the wildland fires could be burning are the “area of interest” as they will not be modified and will retain the native fuels.

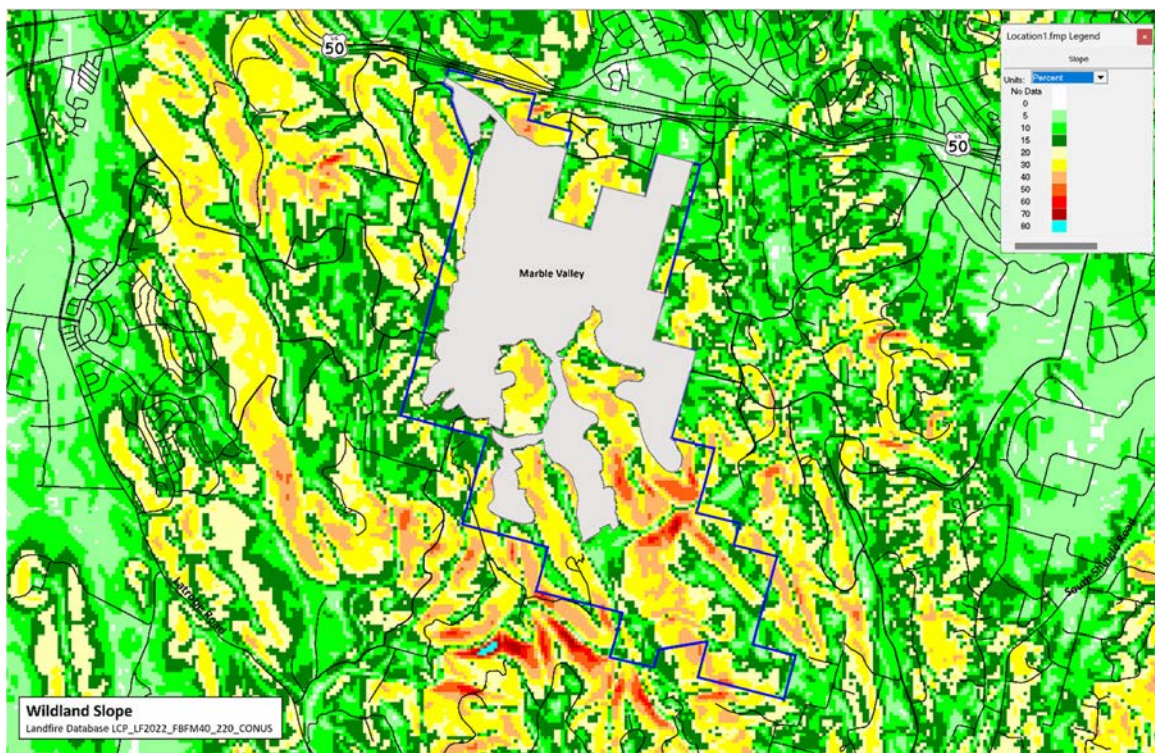

Figure 22 – Slope Map

When averaged over the 30-meter grids, there are no areas with slopes over 50 percent in the interface areas of the Project Site. Manufactured slopes within the development area may be 50 percent or greater in some cases, but they would be in the “managed area” of the development and not in the native areas at the interface. All slopes within the development area which are within 100 feet of a structure will be maintained in accordance with the applicable defensible space standards as required by the California Public Resources Code 4291 by the AHJ.

Aspect and Elevation

Aspect is the compass direction the slope faces. Elevation and aspect can determine how hot and dry a given area will be. Aspect, in particular, often dictates the amount of direct sunlight that wildland fuels will receive in areas where slopes are steep enough to cast shadows. South aspects tend to get more sun than any other aspect, and north aspects, if the slope is significant enough, can be sheltered from the sun's heat and drying effects. This is why, under the right conditions, fuel loading on the northern aspects of some drainages tend to have more fuel. An example from the Project Site is provided in Figure 23.

Figure 23 – Aspect Example

The National Wildfire Coordinating Group (NWCG) speaks to the issue of south-facing slopes in the S190 (Introduction to Wildland Fire Behavior) training materials. It states, “In the Northern Hemisphere, the slopes facing south receive direct sun rays and become hotter than the slopes facing any other direction. The higher temperature on the southern exposures results in lower humidity, rapid loss of fuel and soil moisture, and drier, lighter, flashy fuels such as grass. All of these things add together to make southern slopes more susceptible to fires than northern slopes.” This statement about northern/southern slopes does not apply to wind-driven fires, only slope and fuel-driven fires. When winds are from the N or NE and align with the heavier fuels on the north slopes, the possibility of extreme wildland fire behavior is increased exponentially. (S190 - Introduction to Wildland Fire Behavior, Module 2: Principles of Wildland Fire Behavior, Topic 2: Topography, Aspect, p3, https://training.nwcg.gov/classes/S190/508Files/071231_s190_m2_508.pdf)

The Aspect Map (Figure 24) provides an illustration of how the topography will interact with the Project Site. The Project Site development area is provided in gray for reference. With the

Marble Valley running from north-northwest to south-southeast, the interface aspect is varied and complex. The Elevation Map (Figure 25) indicates how the site rises to the north/east.

Figure 24 – Aspect Map

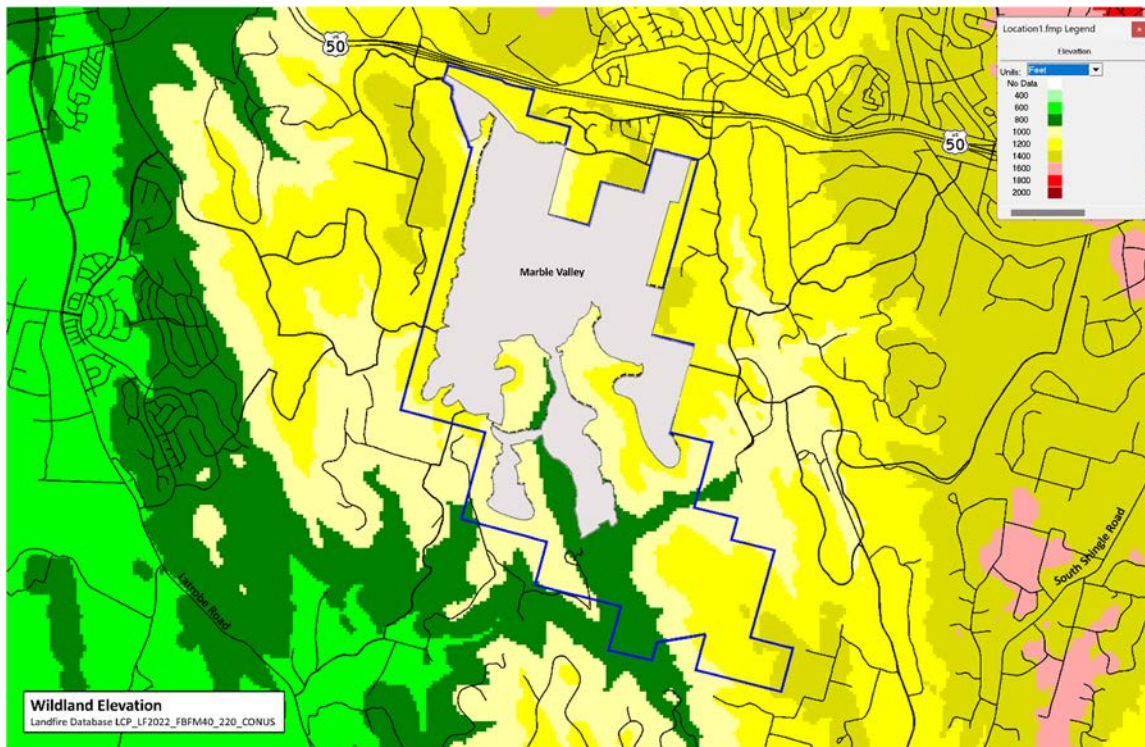

Figure 25 – Elevation Map

Weather

The data from the previously discussed data sites provide the needed assumptions for fire modeling. In addition to the what (data), it is important to understand the why. For the Project Site, the wind has the largest impact on the amount of risk that can be expected from wildland fires. The topography, fuels, and configurations of the interface between the Project Site and the remaining native vegetation are relatively stable (changes are mostly over longer timeframes), whereas weather changes rapidly and often throughout the day, week, months, and seasons.

In the Project Site area, the wind tends to have a large impact on the temperature, relative humidity, fuel moisture, and direction of fire travel. When it comes to wildland fire behavior impacts, winds for the Project Site are driven primarily by two conditions, diurnal flow, and high-pressure areas.

Air moves from high-pressure areas to low-pressure areas. The bigger the difference between the pressures, the faster the air will move from the high to the low pressure. That rush of air is wind. Diurnal flow is created when the land mass heats up (mountains and deserts particularly), creating a low-pressure area (rising air). Cooler air from over the ocean or in the valleys flows to fill these low-pressure areas. To some degree, this occurs every day. Solar heating causes daytime slope/valley winds, and when the night comes, the flow reverses once the air over the ocean/valley is warmer than the air over the mountains. This is depicted in Figure 26 and Figure 27.

Winds caused by high-pressure areas can be extreme, depending on the pressure difference and the topography through which the air flows. Weather fronts and large high-pressure domes can override normal air flow. These winds have various names at different locations around California (as shown in Figure 28). One such event is a high-pressure area to the north/east of the Project Site (often called a high-pressure dome) which sets up air flow from the interior moving toward a low pressure over the ocean. This creates the Diablo and Mono wind events that occur regularly in the central part of California but more often in the fall. Figure 29 illustrates how the flow might occur when the high pressure is east and north of the Project Site.

Figure 26 – Valley Winds Flow

Figure 27 – Slope Winds

Very often, the high pressure moves down the east side of the Sierra Nevada Mountain range. While moving from the north to the south across the high desert area it creates a pressure difference between the sinking dry/cold air in the high-pressure area and the warm rising air over the ocean. The intensity of the wind event is driven by the pressure difference between the high- and low-pressure areas.

Diablo winds tend to warm as they travel across the dry areas to the east (sometimes hot areas). The moisture in the air (RH) can be further reduced by this arid region. The winds are channeled by the topography, and in some cases, the wind speeds are significantly increased by this process. This results in high winds which are hot, dry, and sustained.

At the Project Site, Diablo winds will normally come from the N, NNE, or NE due to the way the air flows through the mountain passes to the north and east of the Project Site.

Most extreme fire behavior in the area around the Project Site occurs during a Diablo wind event. These events dissipate when the high-pressure area moves off to the east or south.

Figure 28 – Foehn Winds in California

Figure 29 – Diablo Wind Event

Historical

California has a history of extreme fire conditions which are often accompanied by winds from the north and east. These winds are the main cause of large fires developing resulting in the loss of structures and lives in California.

In a research paper published in 2018, entitled “A Surface Observation Based Climatology of Diablo-Like Winds in California’s Wine Country and Western Sierra Nevada” the researchers found that Diablo winds occurs not only in the San Francisco Bay area but also in the western Sierra Nevada mountains.

During the October 2017 Northern California Firestorm, Diablo winds were thrust to the forefront of the public consciousness and the broader wildfire meteorology community as a meteorological phenomenon, about which little is known. Our analysis showed that conditions similar to Diablo winds tend to occur at night or in the early morning and are most common during the cool season (late fall through spring). However, our analysis is somewhat constrained by the binary nature of our criteria, and we did not consider the eastern San Francisco Bay Area nor the San Francisco Peninsula. Further research is required to address many issues posed by the sparse RAWS network used in this study, including the production and analysis of a long-term, high resolution downscaled numerical climatology. Of the total number of Diablo-like wind conditions, identified on a daily basis per area, 35% occurred north of the San Francisco Bay area only, 41% occurred in the western Sierra Nevada only, and 23% occurred in both areas. Thus, conditions similar to Diablo winds appear to be just as common in the Sierra Nevada as they are in the area north of the San Francisco Bay Area.

*This implies that they are a regional wind system of Northern California and not a local phenomenon of the San Francisco Bay Area. This indicates that wildfire fighting resources may be required throughout Northern California, including the western Sierra Nevada, when conditions similar to Diablo winds are forecast. Since historical usage of the term Diablo winds was initially confined to the Oakland Hills, it might be more appropriate to refer to Diablo-like wind conditions in the Sierra Nevada as “Diablos del Sierra” or “Bruja” winds. Associated numerical weather simulations (not shown) strongly suggest the downstream linking of mountain wave breaking over the Sierra Nevada to Diablo wind conditions north of the San Francisco Bay Area. **We hypothesize that this mechanism drives Diablo-like wind conditions in both areas and that vertical profiles of wind speed and stability, east of the Sierra Nevada, play a primary role in determining the altitude at which the Sierra downslope jet is lofted off the surface and control of the characteristics of Diablo winds in the San Francisco Bay Area.** (Smith C, Hatchett BJ, Kaplan M. A Surface Observation Based Climatology of Diablo-Like Winds in California’s Wine Country and Western Sierra Nevada. Fire. 2018; 1(2):25. <https://doi.org/10.3390/fire1020025>)*

The weather data around the Project Site does not show significant wind events but it does show pronounced N to NE flow which is likely in these events.

Expected Fire Activity Based on History

Based on the location of the Project Site adjacent to the State Route 50 freeway (source of many fire ignitions) and the proximity of the historic fire corridor to the south and west, coupled with the probability of wind events in the area during times of low moisture (fuel and air), it must be assumed that some fire behavior is going to occur near the Project Site in the near future and continue.

A review of the fire history within 10 miles of the Project Site reveals limited large wildland fire activity in the immediate area around the Project Site. (Figure 30). There is no record of a fire greater than 50 acres on the Project Site within the past 22 years. The nearest fire, over 50 acres, is on the west side of Latrobe Road, approximately 1.5 miles to the west of the project boundary. The increase in fire resources over the past 22 years, coupled with fuels management by CalFire has reduced the frequency of large fires in the general area of the Project Site. Fires can and will continue to occur in the general area due to the nature of the native fuels, but, at least in the past two decades, efforts to minimize these fires have been successful in this area.

To the east of the Project Site (approximately 17 miles) is the location of the Caldor Fire 2021, which started on August 14th and contained on Oct 21st consuming over 220,000 acres or 347 square miles. This fire destroyed 1,003 structures and damaged 81 more. The Caldor Fire started at an elevation of approximately 3,200 feet and burned up to and over the Sierra Nevada divide on down into the Tahoe Basin (Figure 31). This fire was driven by wind, topography and fuel all being in alignment for more of the large runs that the fire made. The conditions that created this level of extreme fire behavior simply do not exist on or near the Project Site. The Project Site is mostly Oak Woodland, whereas the area consumed in the Caldor Fire is mostly Conifer Woodlands. Fire behavior in these two types of woodland is significantly different. The 2021 Caldor Fire (CA-ENF-023040) Burned Area Emergency Response (BAER), Assessment Report Summary, by the Eldorado National Forest and Lake Tahoe Basin Mgt Unit, Pacific Southwest Region, USDA Forest Service, dated October 2021, states:

These dominant vegetation communities are found within the fire perimeter areas: alpine dwarf-shrub, annual non-native grassland, blue-oak/foothill pine, chamise/redshank chaparral, Jeffery pine, lodgepole pine, mixed chaparral, montane chaparral, montane hardwood/ conifer, perennial grassland, ponderosa pine, red fir, Sierran mixed conifer, subalpine conifer, wet meadow, and white fir.

The Project Site has some chaparral fuel areas and once ignited, these fuels will likely burn with great intensity and be difficult to stop. Without historic fire frequency, this chaparral is highly dense and will have a significant dead component as there has been no fire to reduce this load in the recorded large fire database history. Oak Woodlands, on the other hand, do not tend to have the same level of buildup (dead component) resulting in less intense fire behavior. The grass understory of the oaks would have approximately one ton of total fuel load per acre where the chaparral fuels would range from 8 to 15 tons per acre. Large areas of understory shrubs have not been found on the Project Site or surrounding areas nor evidence that it has occurred in the past (dead and downed materials).

Figure 30 – Recent Fire History

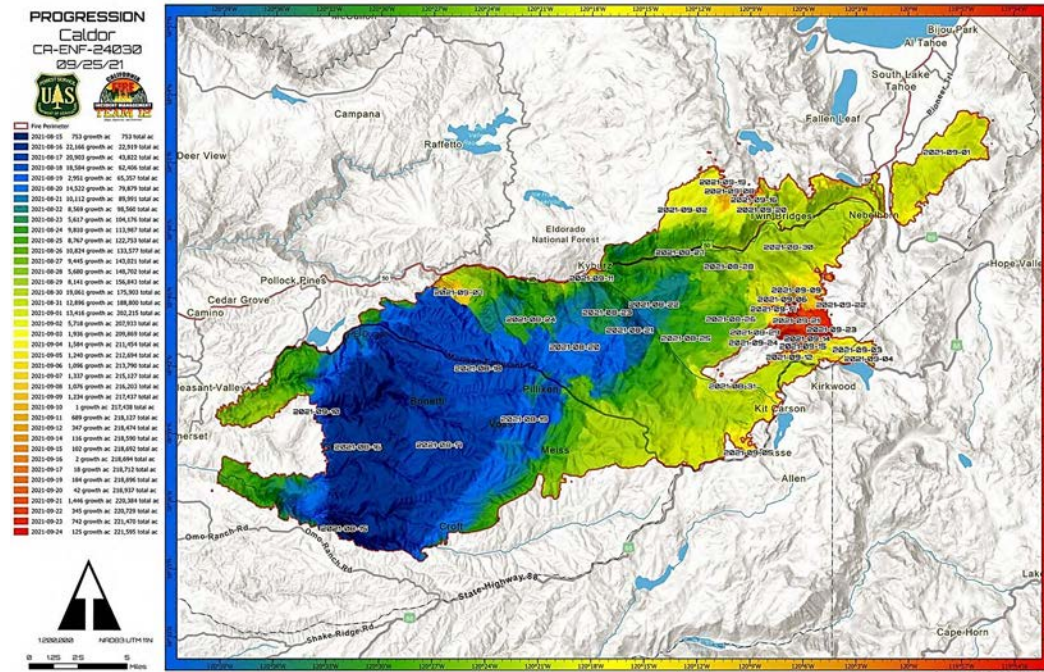

Figure 31 – Caldor Fire Progression Map

Wildfire Risk

The assessment of Wildfire Risk is to examine the hazards in terms of the vulnerability of the assets at risk, the amount of exposure those assets have, and the susceptibility of the assets to wildfire.

Vulnerability

Vulnerability must be examined at multiple levels (Regional, Landscape, Community, and Parcel). At the end of the day, it all comes down to time, distance, and shielding. The amount of time that the fire will impact the area, the distance between the fire and the structures/residents, and the ability of the Project Site to shield its structures/residents from the harmful effects of the fire.

In terms of regional vulnerability, state-wide studies such as the Caltrans Climate Change Vulnerability Assessment Statewide Summary Report 2021 provide a good overview of how different regions of the state of California are expected to be impacted by various climate change issues.

CalTrans completed a statewide Caltrans Climate Change Vulnerability Assessment for the entire State Highway System in 2019. This study involved applying climate data to refine the agency’s understanding of potential climate impacts to the State Highway System, and Caltrans coordinated with various state and federal agencies and academic institutions to obtain the best available climate data for California. Discussions with professionals from various engineering disciplines helped identify how changing climate hazards may affect highways, including their design. The assessment allowed Caltrans to begin to understand how climate change may affect the highway and identified a subset of State

Highway System assets on which to focus future efforts. (<https://dot.ca.gov/-/media/dot-media/programs/transportation-planning/documents/office-of-smart-mobility-and-climate-change/caltrans-climate-change-vulnerability-assessment-statewide-summary-feb2021-a11y.pdf>)

Table 1 (Figure 32 in this report) summarizes the lengths of the State Highway System that passes through the medium to very-high wildfire exposure areas. The Project Site is located in District 3 which is expected to see a 0% increase (none) in the number of State Highway System miles that pass through the medium to very high wildfire exposure areas.

At the Parcel level, the issue of vulnerability is more specific to the actual structure, the amount of defensible space, and the degree of “hardening” of the structure. The current building code standards for structures in the Fire Hazard Severity Zones create the ability for the structure to be more survivable during a fire in the interface. This issue has been studied, and the findings support this view.

The CalFire DSpace (Defensible Space) and DINS (Damage Inspection) Program Analysis program completed an assessment to analyze the effectiveness of Chapter 7A building codes, where they performed a spatial analysis that compared the location of damaged/destroyed commercial and residential structures for the seven largest fires that occurred in 2017 and 2018 (Atlas, Camp, Carr, Nuns, Thomas, Tubbs, and Woolsey) to a 2018 statewide parcel layer. Parcel data, maintained by counties primarily for location and tax purposes, is the most authoritative dataset for information regarding the value and year built of structures in each area.

Table 1: Centerline Miles of Highway Exposed by Year

District	Year			
	2025	2055	2085

CALTRANS CLIMATE CHANGE VULNERABILITY ASSESSMENT STATEWIDE SUMMARY REPORT 2021

Figure 32 – CalTrans Climate Change Vulnerability Assessment Wildfire 2021

This research demonstrates the power of geospatial information to inform research-based decisions. The study demonstrated that structures built to pre-Chapter 7A building codes were more likely to be destroyed in the seven largest fires on record between 2017 and 2018 (Atlas, Camp, Carr, Nuns, Thomas, Tubbs, and Woolsey). The results also demonstrate that residential

structures built in High and Very High Fire Hazard Severity Zones (FHSZ) were less likely to be destroyed by wildfire than those built in Low FHSZ and Urban classifications.

Using over 1,000 pre-fire home inspections, we were able to use real-world data to analyze what factors were most strongly associated with residential structure loss in the Camp Fire. Our findings indicate that wooden roofs, single-pane windows, wooden decks/patios, combustible exterior siding, and a combustible fence attached to a structure are the attributes that are most likely to increase the odds of loss for a residential structure. Structures with double pane windows and patio/carport covers, decks, and exterior siding made of non-combustible materials had a significantly lower chance of structure loss. (CAL FIRE Defensible Space and Damage Inspection Program Data Analysis, August 27, 2019, Steven R. Hawks, William L. Brewer). Compliance with fire resistance construction standards is enforced through defensible space inspections and AB38 inspections.

Between the Regional level and Parcel level are the Landscape and Community levels. The Landscape level is about the vegetation surrounding the development. The U.S. Fire Administration defines this level as:

Wildland landscapes are the dense natural areas that surround the community. These large natural areas can be made up of thousands or even millions of acres. They contain diverse natural fuel types, have undergone various levels of development or management, and are under the oversight of state, federal, tribes, cities or other agencies and organizations. These landscapes require the highest level of collaborative management and partnership. Local fire resources can actively work with the larger land management partners in establishing forest management discussions, project prioritization, strategic planning and implementation efforts. (U.S. Fire Administration, *Wildfire, Healthy Landscapes*, <https://www.usfa.fema.gov/wui/healthy-landscapes/>)

At the Community level are the issues of placement on the topography, fuel modification/defensible space zones, roadside clearance, allowable plant palette, and infrastructure (roads, water, design).

Vulnerability is further divided into Exposure and Susceptibility for the purpose of analysis in the case of wildland fires.

Exposure

Exposure is the result of Likelihood and Intensity combining or occurring simultaneously. A community or structure can be directly exposed to wildfire from adjacent wildland vegetation (direct flame contact, radiated heat exposure, or convected heat exposure), or indirectly exposed to wildfire from embers and home-to-home ignition.

The Project Site will have structures that are constructed in accordance with the current codes (at time of construction) with respect to wildland fire safety. This means that they will be “hardened”, they will have defensible space designed into the configuration, they will be protected with automatic fire sprinklers per NFPA standards, and the entire Project Site will have fuel modification/defensible space zones in accordance with the development requirement of the Fire Department (up to 100’ minimum distance). Direct exposure to a wildland fire is extremely

unlikely, given the requirements applied to this development. Indirect (embers and brands) are likely to occur during a fire in the adjacent wildland. Requirements in the California Building Code Chapter 7A and in the California Residential Code Section R337 provide for ember protection through requirements on vents, gutters, roof valleys, decks, exterior siding, eave protection and several other areas where fire embers might be an issue if they were to land or collect. Leaf guards on gutter is one example of such protection requirements.

The issue of home-to-home ignition is addressed by several risk reduction measures which include: the automatic fire sprinkler systems which are designed to hold the fire to the room of origin, the increased fire resistance nature of the exterior of the structures, the use of double-pane windows with one pane being required to be tempered glass and requirement of Chapter 49 of the Fire Code, and the Public Resources Code Section 4291 which provides for the requirements of the “home ignition zone” to reduce the possibility of structure ignition or fire movement between structures.

The CalFire DSpace and DINS Program Analysis program concluded that “... a higher proportion of parcels built pre-Chapter 7A contained a destroyed structure and a greater proportion of parcels with no damaged or destroyed contained a structure built post 2009”. It also concluded that, “... results also demonstrate that residential structures built in High and Very High Fire Hazard Severity Zones (FHSZ) were less likely to be destroyed by wildfire than those built in Low FHSZ and Urban classifications” which provides some data on the improved outcomes in the zones where construction features are required to be increased for direct and indirect wildland fire impacts.

Susceptibility

The Marble Valley project has been designed in a manner that provides efficient protection from wildfires. Perimeter structures must be protected from radiant heat, direct flame contact, and convected heat to a higher degree than the structures which are in the interior of the development envelope. This protection is achieved through distance, shielding and limiting the amount of fuel near the structures. This shielding of interior structures equates to decreased risk potential.

While the current project configuration is not an Intermix condition (as described previously), the convoluted interface will increase the complexity of the fire behavior closer to the development area but using a “system’s approach” by having fuel modification/defensible space zones interconnected and designed as a whole provide for a significant barrier to fire encroachment into the development areas. The use of defensible space, structure hardening, wildland fuel elimination and modification and placement of the structure on the topography to avoid problematic conditions such as saddles, chimneys, ridgeline wind acceleration, and problematic wildland fuels, creates an overall protection system that is multifaceted and provided for synergistic protections as well as some level of extra protection. These factors are examined in the Fire Safe Plan and addressed in the plan review process for the tract/parcel map. For example, keeping the flaming front of the fire at a distance that will reduce radiant heat issues, but still providing tempered glass in the double-paned windows creates this type of extra protection.

Climatic Conditions

Increasing Temperatures: While temperature increases are likely, according to most of the published materials on climate change in California, the Project Site is not likely to be impacted by this change in terms of wildland fire behavior. The USGS report cited earlier stated, “*Higher temperatures during or in the months prior to Diablo Wind events were generally not associated with the area burned.*” Higher temperatures may well increase the curing rate (rate at which the seasonal growth loses moisture and becomes a dead fuel) of seasonal grasses and increase the decline in fuel moisture during the dry periods, but the wildland fuels which are adjacent to and within the Project Site are relatively drought tolerant. Where they not, they would have already succumbed to the current drought cycles in the region. The temperature is certainly important on an incident-level analysis, but this assessment is considering the worst-case scenario and has already assumed that this has occurred.

(<https://www.usgs.gov/news/research-spotlight-ignitions-and-wind-speed-are-strongest-drivers-area-burned-santa-ana-wind>).

Shifting Wind Patterns: The Diablo/Mono winds will continue to shape wildfire activity across the impacted areas in California. While Fire Weather and Fire Behavior Modelers continue working to determine how these wind events will be impacted by climate change, this analysis has already taken the worst-case wind into account from the current data available.

Precipitation: The amount of rainfall and when it occurs have an extreme impact on fire conditions every year. Drought-impacted fuels are also more susceptible to wildfire. Grasslands in particular have a "boom/bust" growth cycle. Low growth in dry years and high growth in wet years. The Project Site will be resilient to wildfire even in high grassland fuel level years. Wildland fuels in this analysis have assumed an extremely low level of moisture in both the dead and live fuels to account for this aspect of climate change. Changing patterns of rainfall will impact plant growth, thereby altering the amount of fuel for fires.

Changes in Wildland Fuels: After a fire, the lack of precipitation will have an effect on the vegetation that returns. Invasive plants may overtake the native species after a fire. *Most evidence indicates that the strongest impacts of invasive plants on fire regimes in California occur in grasslands and riparian areas.* During this interval where invasives are present, fires may have faster rates of spread but will have lower fireline intensity as they generally have less fuel loading.

When one thinks of fire in California, one immediately thinks of the massive conflagrations that occur in central and southern California chaparral and sage-scrub ecosystems, particularly because of their close proximity to dense population centers. These closed-canopy shrublands—particularly intact chaparral—are in fact, relatively resistant to invasion by non-native species. However, non-native plants are increasingly closely tied to fire dynamics and to ecosystem responses to fire in some regions.

Under natural conditions, chaparral communities retain most fuels in the canopy layer and have relatively long fire intervals (greater than 20 years). Contrary to common perception, foliar tissue does not easily ignite except under super-heated conditions or when leaf tissue moisture is low. However, several weedy forbs and grasses tend to thrive at the disturbed edges of these shrublands along roads, power lines, and fuel

breaks where shrubs are removed. The invasive, annual grasses that often colonize these areas dry out much earlier in the spring than the native shrubs, and with their high surface area to volume ratio, they are more prone to ignition than the native vegetation. Mediterranean grasses such as *Bromus* species and slender oats (*Avena barbata*) are particularly implicated since they act as wicks, spreading fast-moving fire into the canopies of larger shrub vegetation. (Invasive Species and Fire in California Ecosystems, Adam M. Lambert, Carla M. D'Antonio, and Tom L. Dudley, 2010).

The Project Site has both shrub and grass fuels at the perimeter/interface in addition to the treed interfaces. The modeling will show fire activity in the shrub, grass/shrub mixtures, and grass fuels as well as the canopied fuels. All four of these are accounted for in the analysis. This report does not suggest that the Project Site would use prescribed fire for control purposes, but this may be an option to the regional fire agencies.

Shifting Insect Habitat: Insect infestations are rising in response to the changing climate, increasing tree mortality—particularly in the Sierra Nevada regions—and reducing carbon storage according to the Best Practices for Analyzing and Mitigating Wildfire Impacts of Development Projects Under the California Environmental Quality Act published by the California Attorney General in October of 2022. The Project Site has many trees of various species. Insect infestations are not expected to impact the Project Site in any meaningful way. The biological report on the Project Site has addressed this issue.

The management of Oak Woodlands is complex but overall, fire, used correctly, can be a benefit, especially when done under controlled conditions that do not damage the oaks while reducing the overall risk to adjacent areas.

For thousands of years, natural and anthropogenic fire have played an important role in oak woodlands of California. Frequent burning by Native Americans before European settlement resulted in low-intensity fires that maintained open stands of large oaks with little shrub cover, creating a fine-grained mosaic of vegetation patches. Following European American settlement in the mid-1800s, ranchers also conducted burns. Fire history studies indicate that average fire return intervals in oak woodlands in the late nineteenth to early twentieth centuries were from 8 to 15 years, at least in some areas. Fire suppression, begun in the 1940s and 1950s, increased surface and crown fuels, invasion of woody vegetation in the understory, and tree density. The effects of past fires are important to consider when making recommendations for wildlife species. Because these conditions existed for such a long time, they represent conditions under which species evolved and to which they are adapted.

Prescribed fire can be used to reintroduce fire into the ecosystem and co mimic historic fire regimes. Current land ownership patterns complicate prescribed burning plans in many areas, particularly those in urban-wildland interface areas. With careful planning and attention, however, low-intensity prescribed fires can be safely implemented and can achieve the desired results. Moderate- co low-intensity fires rarely kill mature oaks because their thick bark protects them from damage. However, even a low-intensity fire often kills the tops of seedlings, saplings, and small trees, though most will resprout from their base. Most scientific evidence indicates that typical oak woodland understory fires do not adversely affect the majority of terrestrial vertebrate populations. In an

experimental fire that burned over approximately 50 percent of 500 acres (200 ha) of mixed blue oak-coast live oak woodland in central coastal California, there was no appreciable loss of canopy cover, shrubbery, or snags (Vreeland and Tietje 2002). Although grass cover was reduced by 70 percent and downed wood and woodrat houses by 30 percent, there were no substantial or long-term negative impacts to over 150 species of birds, small mammals, amphibians, and reptiles monitored 2 years before and 4 years after the fire. (A Planner's Guide for Oak Woodlands, Second Edition, University of California, Agriculture and Natural Resources, Publication 3491, pages 26-27)

Prescribed fire would only be undertaken by CalFire and is not a tool available to the Project Site but rather a regional option that may be undertaken.

Hazard and Risk Summary

The Project Site is embedded in an area that is adjacent to native wildland fuels on most of the Project Site wildland interface; it will have a wildland interface along the project perimeter. The Project Site is located, for the most part, within the Marble Valley drainage, where most fuels will be oak woodlands with some areas of grassland and chaparral. According to the CalFire database, fires have historically occurred with regular frequency in the regional area around the Project Site, but none have burned over the Project Site that is contained within the CalFire database. Current scientific studies (cited previously in this report) indicate that large fire activity will involve winds pushing the fire to achieve extreme fire behavior. This does not mean that every time the wind blows on a hot day a large fire will occur or that extreme fire behavior is guaranteed based on weather alone. The Highway 50 corridor is a potential source of many fires within the area but also serves as a barrier to some fires (fire perimeter stops at the freeway) where fire conditions (ember cast) do not allow the fire to cross over the freeway and continue to burn. Extreme fire behavior is possible and should be modeled in any scenario in which fire behavior outputs are to be used in this report. This is the basis for the analysis that follows.

The Project Site will need to mitigate against direct fire impingement, radiant heat impingement, convected heat impacts, and ember/brand intrusion, which are all required by the current Regulations. Additionally, modeling will need to demonstrate that the Project Site can be evacuated in a timely manner or that if evacuation is not possible because of the location of the incipient fire, the community will be able to provide "areas of refuge" until it is safe to evacuate, or the fire is suppressed. This analysis is done in a separate document.

Project Impacts Related to Wildland Fires

Ingress/Egress

The Project Site configuration has two access points that will be used on a daily basis for ingress and egress (Marble Valley Road to the Bass Lake Road Interchange (NW Access) and Deer Creek Road/Flying C Road to the Cambridge Road Interchange (N Access)). Five EVA (Emergency Vehicle Access) points are identified, with two serving the Marble Valley site primarily and three serving the Lime Rock site primarily, but all of which could be used by either project if completed. The location of each is shown in Figure 33.

Figure 33 – Evac (Evacuation) Points

These locations will be analyzed in the Evacuation Modeling by the Traffic Engineer using the fire behavior information to determine when each site would no longer be viable for use under fire conditions.

Fire Modeling

Fire modeling will provide a number of outputs that can be used to examine the need and appropriateness of project design features and risk reduction measures. Static modeling is for a given location or condition which does not account for variables over the landscape. The BehavePlus modeling software will be used for this purpose. *“The BehavePlus, Fire Behavior Prediction, and Fuel Modeling System is the most popular and accurate method for predicting wildland fire behavior in pre-fire defense planning. The BehavePlus fire behavior computer modeling system is utilized by wildland fire experts nationwide. Because the model was designed to predict the spread of a fire, the fire model describes the fire behavior only within the flaming front. The primary driving force in the fire behavior calculations is the dead fuel less than 1/4” in diameter; these are the fine fuels that carry the fire. Fuels larger than 1/4” in diameter contribute to fire intensity, but not necessarily to fire spread. The BehavePlus fire model describes a wildfire spreading through surface fuels, which are burnable materials within 6’ of the ground and contiguous to the ground. This type of modeling demonstrates the potential of wind, or a slope-driven fire that could potentially enter the fuel modification zones from the adjacent wildland areas.”* (Andrews, Patricia L. 2014 (published online 2013). Current status and future needs of the BehavePlus Fire Modeling System. International Journal of Wildland Fire 23(1):21-33.)

The Regional modeling in this report will be accomplished using FlamMap, which can simulate potential fire behavior characteristics (spread rate, flame length, fireline intensity, etc.), fire growth and spread, and conditional burn probabilities under constant environmental conditions (weather and fuel moisture). The version used in this report (Version 6.1) includes a FARSITE module (previously a separate application) which allows for outputs on wildfire growth and behavior for longer time periods under heterogeneous conditions of terrain, fuels, fuel moistures, and weather.

Because environmental conditions remain constant when using FlamMap, MTT (Minimum Travel Time), Burn Probability, and TOM (Treatment Optimization Modeling), it will not simulate temporal variations in fire behavior caused by weather and diurnal fluctuations as FARSITE does. Nor will it display spatial variations caused by backing or flanking fire behavior. These limitations need to be considered when viewing FlamMap output using these models in an absolute rather than relative sense. However, these outputs are well-suited for Landscape-level comparisons of fuel treatment effectiveness because fuel is the only variable that changes. Outputs and comparisons can be used to identify combinations of hazardous fuel and topography, aiding in prioritizing fuel treatments.

The FlamMap software creates a variety of vector and raster maps of potential fire behavior characteristics (for example, spread rate, flame length, crown fire activity) and environmental conditions (dead fuel moistures, mid-flame wind speeds, and solar irradiance) over an entire landscape or for specific modeling applications these same outputs are limited to the simulation footprint (MTT and FARSITE). For practical purposes, the most important result of the FARSITE tests to date has been that **spread rates for all fuel models tended to be over-predicted** by the Rothermel spread equation (Rothermel 1972). (<https://firelab.org/project/flammap>). The overall result produces a conservative/worst-case analysis.

Static modeling (BehavePlus)

For the Static modeling, a worst-case fire scenario based on current and expected conditions was used. The modeling input assumptions are:

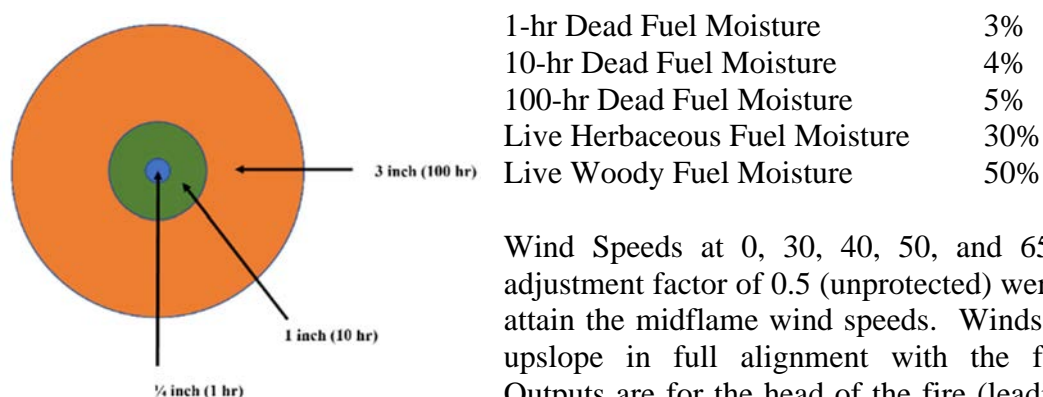

Figure 34 - Dead Fuel Moisture Sizes

Wind Speeds at 0, 30, 40, 50, and 65 mph with an adjustment factor of 0.5 (unprotected) were used for all to attain the midflame wind speeds. Winds are assumed to upslope in full alignment with the fuel and slope. Outputs are for the head of the fire (leading edge) in the direction of maximum spread. Inputs for the modeling are shown in Figure 35.

Inputs: SURFACE

Description		Marble Valley Fuel Comparison	
Fuel/Vegetation, Surface/Understory			
Fuel Model		gr1, gr2, gr4, gs1, gs2, sh2, sh5, s	
Fuel Moisture			
1-h Fuel Moisture	%	3

Wind Adjustment Factor		0.5	
Terrain			
Slope Steepness	%	50	

Figure 35 – BehavePlus Inputs for Worst-case Scenario

The outputs are provided in Appendix B (Modeling Outputs) of this report. In Figure 36 the Flame length outputs for each of the select fuel models are provided with some additional information for perspective. The outputs are highlighted, green for the grasslands, yellow for the chaparral, and blue for the oak shrub understory (healthy oak will have a grass understory if the canopies are closed enough). Flame lengths are provided for the various wind speeds from calm (0 mph) to 65 mph. Statistically, the top end of the wind speed would be around 40 mph from the weather history (only two times over 60 mph in 22 years). This modeling is also assuming it is running upslope (50% slope) in alignment with the wind in a continuous fuelbed.

At 40 mph wind speed, the gr2 produces a 11.6-foot flame length and in the gr4, it is 33.7 feet. Within the chaparral, if the sh5/sh7 models are used, the flame lengths are 42.5 and 39.9 respectively. If the SCAL chaparral fuel models are used for manzanita (SCAL14), the 40-mph flame length is 28.1 feet ,and the Chamise models are less. Using the worst-case scenario, this report will assume the sh5 fuel model as the worst-case.

California-specific fuel models labeled SCAL are Fuel models designed to be used with the BehavePlus software for fuel in southern California. They will likely overestimate fire behavior in the El Dorado region. The SCAL fuel models are species specific (manzanita, chamise, ceanothus) and provide a solid measurement of the fuels ability to burn under specified conditions. They are used here to illustrate the similarities and differences between the fuel specific models and the overall shrub models (sh2, sh5, sh7).

Figure 36 – BehavePlus Output for Flame Length (all fuels)

* Appendix B, provides fuel model descriptions

At zero wind/zero slope, the maximum flame length is only 12.2’ (yellow highlight). Adding a 30-mph wind to the slope nearly triples the flame length to 36.8’. Adding an additional ten mph of wind speed increases the flame length by just over 6 feet at the 40-mph mark and another 5 feet at the 50-mph mark. All three of the grass models (gr1, gr2 and gr4) ran out of fuel. The gr1 fuel is maximized by 30 mph. The gr2 by 40 mph and the gr4 are maximized by the 50-mph wind level and do not increase the flame lengths after that point regardless of the wind increase.

The fuel parameters (the variables for each of the fuel models) for each of the dry climate fuels near the Project Site are provided in Figure 37. These standardized fuel models account for the amount of fuel available for combustion (Fuel Load), the size of the fuel in relationship to the area (SAV ratio or Surface Area to Volume ratio), the fuel bed depth, the level of moisture at which the fuel will no longer combust (moisture of extinction), the amount of live fuel that can be transferred to combustible fuel (Transfer rate), the amount of energy that the particular fuel model can be expected to release (Heat Content) and the amount of dead vs live fuel (live fuel must have the moisture driven off before it can combust).

Fuel model parameters										Dead Component Calculation								
Fuel Model Code	Fuel Model Number	Climate	Fuel load (t/ac)					Fuel model type ^a	SAV ratio (1/ft) ^b			Fuel bed depth (ft)	Dead fuel extinction moisture (percent)	Heat content BTU/lb ^c	Fuel Model Code	100% Transfer

66 feet the chain/80 chains to the mile

gr4 is traveling 16 mph in a 50 mph wind
sh5 is traveling 12 mph in a 65 mph wind

Figure 38 – BehavePlus Output for Rate of Spread (all fuels)

Also of note is the Rate of Spread for each of the fuels under different wind speeds, as shown in Figure 38. Under these extreme conditions, the gr4 fuel is traveling at 16 mph in a 50-mph wind, and the sh5 fuel is traveling at 12 mph in the 66-mph wind. This is extreme fire behavior.

Static modeling has shown that flame lengths of 54.7 feet could be expected if the fire was running upslope, in alignment with the wind, in a continuous fuelbed in a sh5 fuel. BehavePlus 6.0.0 has a chaparral module for refining these calculations.

If this module is run in the same scenario parameters and the maximum value for fuelbed depth is input at 8 feet, and the Dead Load Fraction is set to the maximum value in the model of 43%, and the total fuel load is set to 31 tons per acre, the maximum flame length is 53.9 feet, as shown in Figure 40.

Increasing the dead load actually slows the ROS (see appendix Behave runs).

Inputs: SURFACE

Figure 39 – BehavePlus Inputs/Outputs for Chaparral Fuels Comparison

Based on the worst-case modeling calculations, a maximum flame length of approximately 55 feet could be expected under extreme conditions which are not present on the Project Site currently or in the recent past.

Regional Modeling (FlamMap/MTT)

Using the FlamMap software, it is possible to track the expected path of the fire across the landscape (wildland) and provide rough timeframes for the arrival of the fire front. Specifically, the Minimum Travel Time (MTT) module provides both the path of the fire (major and minor paths) and the expected arrival interval from the starting point of the scenario. In this section, this function will be used to estimate the amount of time that would be available for evacuation at each of the Evacuation Points discussed earlier. Each scenario will be completed for all four configurations (No project, Marble Valley development, Lime Rock development and both developments). The information generated here will be used in the traffic analysis for evacuation timeframes.

The inputs to the FlamMap software are as follows:

- Winds are scenario specific based on the weather history for the area. 99th percentile value was under 40 mph.
- Foliar Moisture Content is set to 100%.
- Crown Fire Calculation Method set to Finney (2004) as this is the method used in the Farsite modeling software, and it the most appropriate for the model as it is being used (minimum travel time).
- Winds are calculated using Generated Gridded Wind (Wind Ninja) rather than generating them in Wind Ninja and importing the results.
- Fuel Moisture settings were fixed using a 3,4,5,30,50 moisture scenario as discussed previously.
- Fuel Moisture Conditions were not used as the moisture scenario is worst-case. Since the lowest recorded moisture is being used, conditioning the fuels will not lower them.
- Maximum Simulation Time was set to 480 minutes as the evacuations would be completed prior to this point.
- Spot Probability was set to 100% to maximize the worst-case conditions.
- Spotting Delay was set to zero to maximize the worst-case conditions.
- Ignition and barrier files are scenario specific but identical for each configuration alternative.

Scenarios have been completed for sixteen locations with various site-specific wind speeds and directions (as indicated in the matrix). Each of these fires corresponds to historic wind data from the weather site discussed previously and summarized in Figures 27 and 31 above. Each scenario has been accomplished for each of the development configurations. Outputs are provided in the appendixes. The outcomes are summarized in the matrix beginning on the next page. The matrix specifies the amount of time that the Evacuation Point would remain viable during the specific scenario.

As indicated in the footer, N/A means that the evacuation point was not used for that scenario. This point could be used for local residents to evacuate but is not used for the Project Site modeling. The single * indicates that the time shown is valid only if the infrastructure from the adjacent project was constructed and available. The double ** indicates that the time value (number in the cell of the matrix) may be based on the travel route rather than the actual evacuation point. This applies when the route would be back into the fire path in a timeframe that would make this route unsafe.

N/A is not accessible. None is no time restriction. Numbers are in minutes (time to egress point no longer viable)

* Only applies if infrastructure (roads) from adjacent project is provided (even if balance of the project is not completed)

** - Based on travel route impacts not Evac Point

Modeling Summary

In a worst-case scenario for the static fire modeling, flame lengths of 55' +/- may be possible when the fire is running upslope, in a continuous fuel bed (chaparral fuel), in line with the wind, on a very dry hot day. This is based on six-foot chaparral fuel beds (Sh5 fuel) and eight-foot beds in the Chaparral specific model run.

Using the Minimum Travel Time feature of FlamMap, it is possible to project the time it might take for a given fire scenario to travel the distance from the origin to each of the evacuation points within the Project Site and when they might impact the Evacuation Points. These results are provided for each scenario in the appendix and summarized in the matrix.

Figure 40 – Example Scenario Modeling Output

In all scenarios, burn-through of the community is not modeled or expected given the fuel modification/defensible space zones, hardened structures and restrictions on vegetation which will be in place by the Regulation and standards required by the Fire Department for new development within the Very High Fire Hazard Severity Zones. This does not preclude structure ignition or damage on the perimeter of the community in this modeling, only that the fire will not continue through the community.

In a recent study (2019) researchers found that housing density plays a role in the number of structures which are damaged or destroyed in wildland fires:

Looking at fire ignitions, large fires, and structures burned, we explored the importance of climatic and human variables for explaining fire and structure loss patterns across three diverse California landscapes, under current and future

climate (hot-dry or warm-wet) and land use (rural or urban residential growth) scenarios. Across regions, we found that housing and human infrastructure were more responsible for explaining fire ignitions and structure loss probability. Large fires were better explained by climate, topography, and fuel variables. The differing strengths of these relationships interacted with the climate and land use scenarios, resulting in variability across regions in the relative importance of climate and housing patterns on fire and structures burnt. Focusing only on empirical housing density and structures burnt, we found that most structure loss occurred in areas with low housing density (from 0.08 to 2.01 units/ha), and as such, expansion of rural residential land use generally increased projected structure loss probability in the future. Both the historical results and the future projections highlight that future changes are likely to be complex and will result from a range of interacting factors. Climate change will be important to consider for managers and policy makers in some, but not all regions. In all areas, land use change merits increased attention, as local policy decisions can influence future patterns of development and exposure of structures to risk of loss in large wildfires. Syphard, A. D., Rustigian-Romsos, H., Mann, M., Conlisk, E., Moritz, M. A., & Ackerly, D. (2019). The relative influence of climate and housing development on current and projected future fire patterns and structure loss across three California landscapes. *Global Environmental Change*, 56, 41–55. <https://doi.org/10.1016/J.GLOENVCHA.2019.03.007>

The findings of this research make sense in that denser developments will have a defined interface (rather than an intermix condition), overall vegetation within the community is generally less and is managed within 100 feet of the structures. These management areas tend to overlap in denser communities, forming a homogenous area within the wildland where conditions for continue burning are greatly reduced or eliminated. Add to this, structures which are hardened to radiant and convected heat, have ember protects and are set far enough from the native fuels to not have direct flame contact from the wildland makes the ignition less likely. In the event that a structure was to ignite, all of the residential units and support structures of any real size are protected by automatic fire sprinklers which have a history of holding fires to the room or area of origin in most cases, make the likelihood of a conflagration or community burn-through unlikely.

The size, location and configuration of the Project Site make it unlikely that a fire will impact the entire Project Site at a single time, but rather the fire will impact sections of the project interface over a period of time which will allow for resources to be redistributed and for evacuation opportunities after the fire front has passed a specific location. Travel within the Project Site should be viable at all times, given the distance from the wildland fuels and the protection features which will be provided. The fire scenarios which have been modeled are extreme and the results indicate the fire will be traveling at a rate faster than fire suppression activity will allow for control lines. The fire department would be expending efforts to keep evacuation routes open, protect structures where it was safe to do so and to work on indirect actions in an effort to have a positive effect on the fire path and the assets at risk. Interior areas of the community not shown as areas burned (colored areas in Figure 40 and in the appendixes) will be capable of use as “areas of refuge” when not in the direct line a travel for the fire.

Water Supply and Infrastructure

No water delivery facilities are present on the Project Site. El Dorado Irrigation District (EID) provides potable water to over 100,000 people in El Dorado County through two primary interconnected water systems in its service area—the El Dorado Hills system and the Western/Eastern system. The El Dorado Hills water system obtains its primary supplies under rights and entitlements from Folsom Reservoir, while the Western/Eastern system derives its supplies from sources under rights from the South Fork American River and Cosumnes River watersheds. The Project Site lies within EID’s El Dorado Hills supply area.

The El Dorado Irrigation District 2019 Water Supply and Demand Report and 2020 Urban Water Management Plan detail water supply and the timing and need for various improvements throughout the district. Based on reviews of these recent reports and the revalidation memorandum, the data and supply availability conclusions in the WSA relating to water supply and consumption remain valid, and water is available for the Project Site for residential use, irrigation, and fire flow.

The specifics of the water supply are well documented in the Project Site EIR.

El Dorado Hills Fire Department

TABLE B105.1(1)
REQUIRED FIRE FLOW FOR ONE- AND TWO-FAMILY DWELLINGS, GROUP R-3 AND R-4 BUILDINGS AND TOWNHOUSES

FIRE-FLOW CALCULATION AREA (square feet)	AUTOMATIC SPRINKLER SYSTEM (Design Standard)	MINIMUM FIRE FLOW (gallons per minute)	FLOW DURATION (hours)
0-3,600	No automatic sprinkler system	1,000	1
3,601 and greater	No automatic sprinkler system	Value in Table B105.1(2)	Duration in Table B105.1(2) at the required fire-flow rate
0-3,600	Section 903.3.1.3 of the <i>California Fire Code</i> or Section 313.3 of the <i>California Residential Code</i>	1,000	1
3,601 and greater	Section 903.3.1.3 of the <i>California Fire Code</i> or Section 313.3 of the <i>California Residential Code</i>	½ Value in Table B105.1(2) (min 1,000 gpm)	2

MAJOR SUBDIVISIONS (5 Parcel or Greater)

0-3,600	Section 903.3.1.3 of the <i>California Fire Code</i> or Section 313.3 of the <i>California Residential Code</i>	500	1
3,601 and greater	Section 903.3.1.3 of the <i>California Fire Code</i> or Section 313.3 of the <i>California Residential Code</i>	½ Value in Table B105.1(2) (min 750 gpm)	1

TABLE B105.2
REQUIRED FIRE FLOW FOR BUILDINGS OTHER THAN ONE- AND TWO-FAMILY DWELLINGS, GROUP R-3 AND R-4 BUILDINGS AND TOWNHOUSES

AUTOMATIC SPRINKLER SYSTEM (Design Standard)	MINIMUM FIRE FLOW (gallons per minute)	FLOW DURATION (hours)
No automatic sprinkler system	Value in Table B105.1(2)	Duration in Table B105.1(2)
Section 903.3.1.2 of the <i>California Fire Code</i>	25% of the value in Table B105.1(2) ^b	Duration in Table B105.1(2) at the reduced flow rate

b. The reduced fire flow shall be not less than 1,500 gallons per minute.

In accordance with the amended Fire Codes (2020) for the respective Fire Department areas, fire flow requirements for the Project are shown to the left and on the next page.

The water system will be designed and constructed in accordance with the adopted fire code(s), NFPA standards and local requirements as stated in the fire departments adopted and published requirements. For example, El Dorado Hills Standard #D-003 Water Supplies for Suburban and Rural Fire Fighting - 3/23/2022.

Where portions of the water system are not gravity fed, emergency power will be provided for the duration required in the code.

Figure 42 - Amended Fire Flow Requirements for EDCFPD Area

According to EID’s 2022 Water Supply and Demand Report (El Dorado Irrigation District, 2022), the district has available water supply in the Western/Eastern supply area of approximately 30,580 AF (acre feet). EID’s adopted Integrated Water Resources Master Plan (HDR, 2013) describes new water supply and transmission infrastructure necessary to increase the availability of water supply for the Western/Eastern Supply area.

An overall potable water system is in place for the El Dorado Hills and the Cameron Park communities, including off-site transmission mains, storage tanks, and booster stations. Development of the Plan Area requires the construction and extension of transmission and distribution water mains that will be constructed in phases. (Refer to Figure 43.)

Components of the overall water system include off-site transmission mains, on-site and/or off-site storage tanks, booster stations, distribution mains, and laterals. The installation of water

While electrical lines are the cause of fires all over the state, utilities in the state of California are taking steps to increase the safety of all power lines by:

1. Undergrounding distribution lines
2. Improving safety on transmission lines through the replacement of equipment before it fails
3. Increased routine inspections.
4. The use of “covered conductors” rather than “bare wire” as has been used in the past.
5. Expanded line clearance, increased hazard-tree assessments and removals, ensuring adequate cleared brush at the base of poles/towers.
6. Public Safety Power Shut Offs during high-risk weather events.
7. Installing and monitoring of over 2,000 Remote Automated Weather Stations, expanded use of Artificial Intelligence/Machine Learning capabilities (AI/ML) for improved forecasting and the installation of High-Definition Cameras for real-time monitoring of high-risk areas during extreme weather events.
8. Installation of Sectionalizing Devices and Fast Acting Fuses to decrease the risk of fire inducting events.

The above measures are regional actions which should result in a decrease in fire caused by the overall electrical grid. Many of the fires caused by the electrical distribution system occur during extreme fire weather conditions. Any reduction in these types of fires within the region increases the overall protection to the Project Site by lowering the probability of a large fire.

Fire Protection Resources

Impacts During Construction

Prior to combustible construction on site the Fire Department requires that “all-weather” fire department access roadways, fire hydrants (or approved water source alternative), and initial fuel modification/defensible space zones (bare earth is acceptable at this point) are installed and approved prior to the “framing stage”. Prior to C of O (certificate of occupancy), the Fire Department requires that all fire department life safety systems (fire sprinklers, standpipes if applicable), fire lanes, street signs, addressing, wayfinding if appropriate, defensible space requirements and structure hardening as required by the various laws, codes, ordinance and standards enforced by the fire department and building/planning agencies be in place, tested, inspected and approved.

Impacts Over the Life of the Project

Maintenance requirements for each of the safety systems or devices are assigned to specific entities (homeowners, Home Owner’s Associations (HOA), Local government). Repair/replacement and maintenance of these systems will be established in the CC&R’s for the homeowners and HOA(s), while the local governmental agency is responsible for the public improvements in the Right of Way (ROW). In some cases, a Zone of Benefit (ZOB) may be established to provide for different levels of service, or to raise additional revenue within specific areas of a county service area.

The responsibilities and funding source for the common areas (not in the ROW) are to be set in the CC&R’s. Unless otherwise provided in the CC&Rs, homeowners are responsible to maintain

improvements to their fee-title properties while HOA's maintain common areas and other improvements either owned by the HOA or controlled by the HOA if established by the CCR&s.

EVA's (Emergency Vehicle Access) will be maintained in perpetuity by the appropriate entity or entities which are benefited by the improvement. In the case of public streets or ROW's this will be the governmental agency which owns the underlying property. For improvements on private property, the HOA(s) or other legal entity (such as a private property owner or ZOB) is responsible for the common area(s) on which the improvements (EVA) have been made.

Fuel modification/defensible space zones, installed automatic fire sprinklers (except the NFPA13D system in one and two-family dwellings) and defensible space are inspected by the fire department on a routine basis (annually or bi-annually in most cases) and in the case of fire sprinklers (NFPA 13 and 13R), they are inspected and certified by third-party vendors on a five year interval.

Fire Suppression Resources

Fire Department resources and capabilities have been discussed in various documents over the development of the Project Site. The following is a summary of those overall resources and capabilities:

Fire protection services in El Dorado County are provided by 13 separate fire districts, one city fire department, the California Department of Forestry and Fire Protection, and the U.S. Forest Service. Two fire protection districts serve the proposed project site: the El Dorado Hills County Water District (which includes the EDHFD) serves the western portion of the project site, and the El Dorado County Fire Protection District (also referred to as the El Dorado County Fire District or El Dorado County Fire) serves the eastern portion. The final map boundary line must follow the existing fire boundary line to insure no residential or commercial lot is split between two fire districts.

El Dorado Hills Fire Department

The EDHFD covers approximately 112 square miles and serves a population of approximately 55,000 with five fire stations and five response zones (El Dorado Hills Fire Department 2020). The department currently has 76 paid personnel (El Dorado Hills Fire Department 2020). As stated in the Regulatory Setting, Policy 5.1.2.2 in the County General Plan identifies that the minimum level of service for fire district responses should be an 8-minute response to 80 percent of the population for a Community Region, and a 15–45-minute response time for a rural region (El Dorado County 2004). Fire Station Number 86 would serve the western portion of the project area. Fire Station Number 86, which lies approximately 1 mile northwest of the project site, has average response times in the plan area of between 4:28 and 5:27. (Hobert pers. comm.). This fire station is staffed with three fire personnel and is equipped with an advanced life support engine and a wildland urban interface engine (Hobert pers. comm.).

The El Dorado Hills Fire Department Five Year Plan for 2013–2018, adopted in October 2013, serves as a projection for the department’s growth over the next 5 years. This is the most recent five-year plan in effect at the time of publication of this Draft EIR. The plan identifies historical and projected residential and commercial development in the El Dorado Hills Fire Department’s (EDHFD) service area, including the location, total projected units, and population associated with residential development and the square footage and location of anticipated commercial development. The plan summarizes annual incidents and calls for service from 2007 through 2017. The plan identifies existing staffing and uses that, along with the development data, to predict future department staffing needs. In addition, it describes existing and proposed facilities and apparatus, including a proposed 21-acre training facility in the El Dorado Hills Business Park (El Dorado Hills Fire Department 2013).

The plan includes maps showing driving times from each of the fire district’s existing stations and the proposed Business Park Station to the district’s more populated areas. The maps do not reflect total response time, which includes reporting the emergency and call processing (El Dorado Hills Fire Department 2013). Driving times depicted on the maps range from 4.5 to 6.5 minutes (El Dorado Hills Fire Department 2013).

The plan describes existing and future department revenues and their sources, including property taxes and development fees. The plan notes a decrease in property tax revenues over the past 5 years due to the economic downturn and associated lack of development and indicates an increase beginning in the 2013–2014 fiscal year (El Dorado Hills Fire Department 2013). EDHFD imposes development fees on all new development to ensure the development pays its share of capital costs associated with adequate facilities and equipment to mitigate its impacts and to ensure maintenance of the level of service provided to existing residents within its jurisdiction. The department has historically imposed development fees on a per-dwelling-unit basis, converted to a per-square-foot fee for industrial and commercial development (El Dorado Hills Fire Department 2013). The plan reflects a new fee structure, consistent with that used by the Sacramento Metropolitan Fire District and based on input from the other El Dorado County fire districts, which is based on square footage for both commercial and residential applications (El Dorado Hills Fire Department 2013). While the department indicates that a development impact fee of \$1.29 per square foot is justified, its Board of Directors elected to assess development at a rate of \$1.16 per square foot and recover the remainder from its general reserve funds, reserving the option to adjust the fee upward or downward in the future based on its annual review (El Dorado Hills Fire Department 2013).

EDHFD would serve the western portion of the project site while the El Dorado County Fire Protection District would serve the eastern portion. The VMVSP includes a location for a future EDHFD fire facility in the southwest portion of the project site, near the border with China Diggins Road (Marble Valley

Company LLC 2020). The project proponent and EDHFD would determine the exact location and parcel size in the future, should the need arise, including any utilities and infrastructure needed to serve the facility and would prepare a separate CEQA document at that time.

The proposed project site would be served by the closest fire station, Fire Station 86 of the EDHFD. This station serves 2,998 homes and is located approximately 1 mile from the project site on Bass Lake Road (El Dorado Hills Fire Department 2012). Based on the annual report of the EDHFD for Code 3 Emergencies, Fire Station 86 response times are under 7 minutes (El Dorado Hills Fire Department 2012). The standard for the fire department is a 6-minute travel time, 90 percent of the time for all emergency calls (Lilienthal pers. comm.). Because the proposed project is proposing to annex to a Community Region, it would have to meet the 8-minute minimum response time for 80 percent of the population. The EDHFD anticipates it would meet a 6-minute response time for the VMVSP area even without the additional fire station included in the project because of the proximity of Fire Station 86 (Lilienthal pers. comm.). Thus, based on the County General Plan minimum requirements and the fire department standards, the level of service currently achieved would be sufficient.

El Dorado County Fire Protection District

The El Dorado County Fire Protection District serves 281 square miles and has a population of 75,000 with 14 stations (El Dorado County Fire 2020). The department consists of 74 total personnel (Alvarado pers. comm.). Station 28 would serve the eastern portion of the project site. This fire station is located approximately 4 miles northeast of the project site, and the average response to the project site would be approximately 12.5 minutes (Alvarado, pers. comm.)

The El Dorado County Fire Protection District Five Year Plan 2011–2016 serves as a set of guidelines to address identified needs over a 5-year period. The district's vision and guiding principles, history, organization, and sources of revenue are outlined, and the district's facilities, apparatus, and response to incidents are described. The plan uses this information to identify personnel and equipment needs as well as methods to address those needs.

The plan indicates that the El Dorado County Fire Protection District—also referred to as the El Dorado County Fire District or El Dorado County Fire—responds to 4.6 times more calls than the average number of responses of all 14 other fire agencies in El Dorado County (El Dorado County Fire Protection District 2011). The plan includes bar charts that show a 15.7 percent increase in call volume over the previous 8 years, and a 19 percent reduction in average response time since 2002, with an average response time of 9 minutes and 19 seconds (El Dorado County Fire Protection District 2011).

The plan also describes existing and future department revenues and their sources, including property taxes and development fees. Property taxes constitute

the district's primary source of funding; the district receives 13 percent of the 1 percent Ad Valorem Tax collected by the County within the district's boundaries (El Dorado County Fire Protection District 2011). The plan notes a decrease in property tax revenues beginning in the 1992–1993 fiscal year, associated with the transfer of 10 percent of each special district's property tax revenue to school funding through the Educational Revenue Augmentation Fund, and indicates that the annual loss to the district exceeds \$1.1 million dollars (El Dorado County Fire Protection District 2011). In addition to the Ad Valorem Tax funding, the district receives funding from voter-approved special taxes in some areas of the district; this funding provides approximately \$510,000 of additional annual revenue (El Dorado County Fire Protection District 2011).

Fire Station 28, located approximately 4 miles from the project site on Ponderosa Road in Shingle Springs, is the closest El Dorado County Fire Protection District fire station to the project area. It serves Red Hawk Casino and the communities of Shingle Springs, South Cameron Estates, and Crazy Horse. The average response time for the El Dorado County Fire Protection District from 2002 to 2010 was approximately 9 minutes, and approximately 8:43 minutes in 2010 (El Dorado County Fire Protection District 2011:18). Response times have been reduced by 19 percent since 2002. Although this is slightly over the 8-minute minimum response time, several factors would address this deficit. Because the project area would be served by the EDHFD and the El Dorado County Fire Protection District, the proximity of the project site to the nearest fire stations, and the inclusion of a future fire station on the project site, it is anticipated that the County General Plan requirements would be met. No new fire protection facilities beyond those planned within the project or alterations to existing facilities would be needed.

Utilizing the “boundary drop” agreement, which is in place between the local fire departments, the closest resource responses to an emergency regardless of jurisdiction, E89 from Cameron Park (3200 Country Club Drive, Cameron Park) could be the closest fire department resource, if available.

El Dorado County Fire Protection District also owns a vacant parcel APN 119-295-002 located in the area of Crazy Horse Rd and Hemmingway Ct on the western side of the district and immediately north of the Project Site. Potential future development of this parcel would add to the resources available in the event of an emergency.

Operational Considerations

How to complete the evacuation, when to evacuate, how long it will take to get the last person out of harm's way, and to where are they evacuating, are all factors that need to be considered when making tactical decisions on wildfires. Normally the majority of the effort is put towards fire suppression on the active fire line if conditions warrant it; indirect attack if not. When people are in “harm's way,” the situation shifts dramatically. The protection of the egress pathways, the structures themselves, and the area where refuge can be found become the priority.

The decision to “Shelter in Place” is never the first choice and is not a first choice for the Project Site. Getting people “out of harm’s way” is always the preferred option. Not every scenario can be anticipated, there will be scenarios that would require the incident commander(s) or field officer of the fire and law enforcement agencies to decide on how to protect the citizens when emergent conditions arise. Figure 44 provides a simple decision tree for evacuation vs. protecting people in place.

Evacuation is always the preferred option but sometimes, circumstances may generate conditions where moving an “at risk” population will place them in more danger. It should be noted that most evacuation scenarios are generated by large fires burning into communities. These fires would have already been burning for a period of time and would, no doubt, have been discovered. Emergency personnel would be working on the decisions below to determine where evacuation is warranted. The modeling shows that if the fire reaches certain points, evacuation is not a likely choice. If there is not enough time to safely move the population at risk to an uninvolved/safe area, consideration of where to best protect them is the next action on the decision tree.

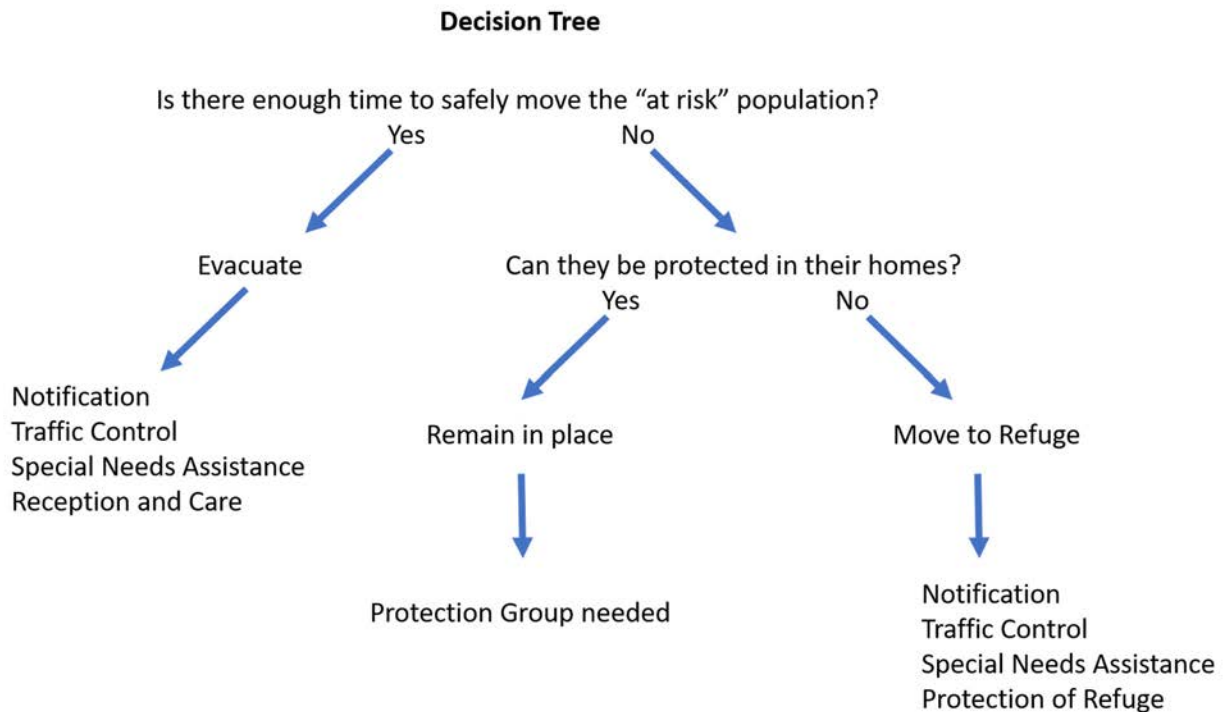

Figure 44 – Evacuation Decision Tree

In planned communities, a legal entity (normally an HOA) is responsible for common areas and the maintenance of community resources. This often includes lighting, landscape, parks, pools and in some communities’ roads, bridges, and open spaces, and when the housing products include, joint land ownership, and even property insurance. Where the community has been designed and developed with wildland fire defenses such as fuel modification/defensible space zones, greenbelts, roadside clearance for evacuation routes and/or special maintenance areas within the community, it is the HOA or other legal entity that is responsible for maintaining

these common features. As such, there is a high probability that this ongoing maintenance will occur as required and as stated in the organizational documents which were put in place when the community was established. It also makes a single entity accountable and simplifies the inspection process as well as streamlines the communications process (notices, code and standards updates, compliance, verification of maintenance).

The building and fire codes and some county and state wildland fire regulations are based on requirements for the land or building owner. As such, there is not necessarily an equal level of compliance at each and every structure, even if they were constructed at the same time, under the same requirements. In wildland fire safety, when structures are not separated by a large distance (30 feet or more), the risk to one structure can be caused by the risk to the adjacent structure even when the first owner has done everything right in terms of wildland fire protection. In planned communities, this is not the case. Common areas are managed as one entity, and the HOA has the power to make each homeowner comply with the regulations adopted by the local fire authority as an obligation of its fiduciary function to keep the entire community safe. This is why planned communities are significantly different in the ability to keep the community safe from wildland fires. This is why a “systems approach” is possible.

This “systems approach” begins with the community design. Larger, planned communities generally tend to use a defined interface rather than an intermix with respect to the wildland perimeter of the development.

Cluster development (higher density with more open space) with defined perimeter protection provides for a “protective bubble” around the development. By controlling the interior (vegetation, configuration and defensible space) and providing an adequate distance (fuel modification/defensible space, greenbelts, selected agriculture crops (vineyards, certain types of orchards, row crops), fuel breaks and fire breaks) the combination of these elements creates a system for the protection of the community.

The current codes and standards coupled with the design of the current fuel modification/defensible space zone requirements provides for a community in which fire is unlikely to burn through the community (burn-through) when all portions of the system are in place and functioning as designed.

Provisions are in place to allow for approved maintenance in the fuel modification/defensible space areas so that the safety margin can be maintained.

2.1.2 Fire Safe Activities Exemption Actions taken pursuant to an approved Fire Safe Plan for existing structures or in accordance with defensible space maintenance requirements for existing structures as identified in California Public Resources Code (PRC) Section 4291 are exempted from the mitigation requirements included in this ORMP. Oak resources impacts for initial defensible space establishment for new development are not exempt from the mitigation requirements included in this ORMP. After establishment of defensible space for new development, maintenance of that defensible space thereafter is exempt from the mitigation requirements included in this ORMP. In addition, fuel modification

activities outside of defensible space areas that are associated with fuel breaks, corridors, or easements intended to slow or stop wildfire spread, ensure the safety of emergency fire equipment and personnel, allow evacuation of civilians, provide a point of attack or defense for firefighters during a wildland fire, and/or prevent the movement of a wildfire from a structure to the vegetated landscape, where no grading permit or building permit is applicable, are exempted from the mitigation requirements included in this ORMP. (El Dorado County Oak Resources Management Plan, September 2017, Page 6)

Risk Reduction Measures

Risk Reduction measures which are required by codes, ordinances and standards include:

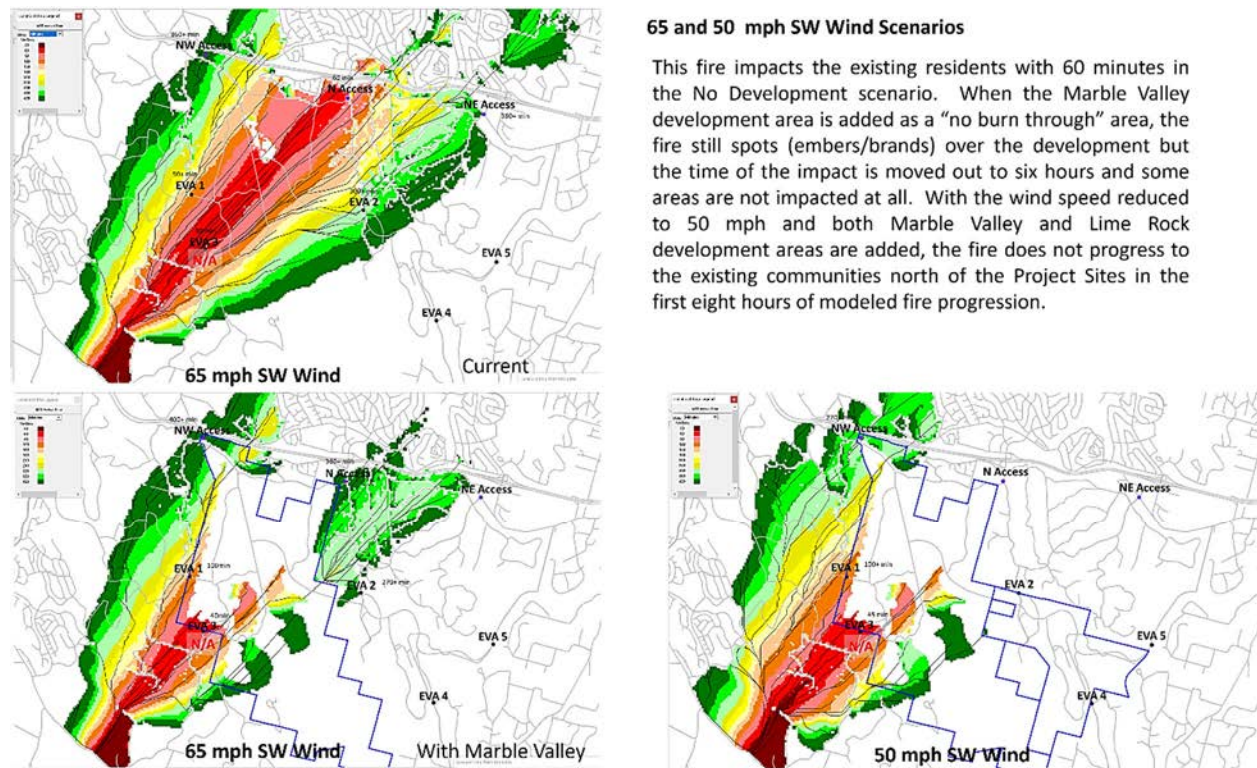

- a) All dwelling units and most large commercial buildings will be protected with automatic fire sprinklers. (Fire department plan check and inspections ensure compliance)
- b) The Project Site has increasing housing density and used a consolidated design to reduce or eliminate, where possible, wildland fuels within the interior of the Project Site and keep the edge of the Project Site as an identifiable interface with appropriate fuel breaks, fire breaks and fuel modification/defensible space zones. (Fire department plan check and inspections ensure compliance)
- c) The Project Site has been designed to avoid and minimize low-density urban development patterns or leapfrog-type developments (i.e., those with undeveloped wildland between developed areas). (Fire department plan check and inspections ensure compliance)
- d) Decreasing the extent and amount of “edge,” or interface area, where development is adjacent to undeveloped wildlands. (Fire department plan check and inspections ensure compliance)
- e) The Project Site has/will create buffer zones and defensible space within and adjacent to the development, with particular attention to ensuring that vegetation will not touch structures or overhang roofs. The Project will establish the legal obligations within the CCR’s to ensure that defensible space measures are retained over time. (Implementation of Fire Safe Plan, Fire department plan check and inspections ensure compliance)
- f) Undergrounding of power lines will be accomplished in the entire Project Site. (Fire department plan check and inspections ensure compliance)
- g) The Project Site design attempts to limit development along steep slopes and amidst rugged terrain, so as to decrease exposure to rapid fire spread and increase accessibility for firefighting. Sites which have wildland fuels below (lower than the project structures) will have additional protections provided with radiant heat walls, increased built-in fire protection features and/or placement of the structure so that the impacts of “underslung fuels” are reduced to a level of acceptable risk. (Implementation of Fire Safe Plan, Fire department plan check and inspections ensure compliance)
- h) Fire hardening structures and homes in accordance with Chapter 7A of the Building Code, Section R337 of the Residential Code and the specific requirements of the fire department during the development review process for the site-specific locations.

(Implementation of Fire Safe Plan, Fire department plan check and inspections ensure compliance)

- i) Siting structures and features to maximize the role of low-flammability landscape features and roadways that may buffer the development from fire spread. (Implementation of Fire Safe Plan, Fire department plan check and inspections ensure compliance)
- j) The Project will expand existing fire resources in the region (new fire station site within the development). (Developer Agreement with Fire Department, participation in fire district)
- k) Placement of development within the existing or planned ingress/egress and potential evacuation routes to efficiently evacuate the project population and the existing community population, consistent with evacuation plans, while simultaneously allowing emergency access. (Implementation of Fire Safe Plan, Fire department plan check and inspections ensure compliance)

Additional Regional Benefits

In addition to the project specific risk reduction measures, the project, in and off itself, provides for some additional protection to existing communities where it provides a buffer of non-wildland fuels between some of the fire scenarios and the existing communities. Using the modeling results to illustrate this point, in Figure 45, the graphic provides a comparison of the fire behavior for a “No Development” scenario with a scenario where the Marble Valley project has been completed. Significant additional time is provided to the existing communities to the north of the Project Site. The comparison then provides the modeling for a fire with 50 mph winds rather than 65 mph winds from the SW (same fire origin). At 50 mph, the fire does not continue to burn across the Marble Valley site but does continue into the adjacent communities to the north as with the previous scenarios. Each scenario has its own impacts and benefits but, in most cases, where the new development is between the origin of the fire and the existing community, there is a benefit in terms of additional time to evacuate or the fire simply not getting the existing community at all.

65 and 50 mph SW Wind Scenarios

This fire impacts the existing residents with 60 minutes in the No Development scenario. When the Marble Valley development area is added as a “no burn through” area, the fire still spots (embers/brands) over the development but the time of the impact is moved out to six hours and some areas are not impacted at all. With the wind speed reduced to 50 mph and both Marble Valley and Lime Rock development areas are added, the fire does not progress to the existing communities north of the Project Sites in the first eight hours of modeled fire progression.

Figure 45 - Example of Regional Benefits (Wildfire)

With respect to the tasks as outlined in the California Attorney General’s “*Best Practices for Analyzing and Mitigating Wildfire Impacts of Development Projects Under the California Environmental Quality Act*” the report has the following conclusions:

- 1. Determination of project impact will substantially impair an adopted emergency response plan or emergency evacuation plan;**

The Project Site’s general area does not have an adopted emergency evacuation plan. The emergency response capabilities will be enhanced with the addition of a new fire station and improvements to the public roadways. The evacuation analysis for this project will be the first formal process that can be found in searches of the available records (see Fehr and Peers Evacuation Analysis for details).

From a wildland fire behavior perspective, the Project Site will not substantially impair an adopted emergency response plan or emergency evacuation plan. Project Site specific plans will be completed as an integral part of Resident Information and Community Communications efforts by the Project Site sponsors, builders, and the ultimate HOA’s who will have the ongoing responsibility for this information.

- 2. Determine the project-specific Wildland Fire Hazard and Wildland Fire Risk to quantify issues that may exacerbate wildfire risks, and thereby expose project occupants to pollutant concentrations from a wildfire or the uncontrolled spread of a wildfire;**

This report has examined the project-specific Wildland Fire Hazards and the resulting Risks after the risk reduction measures are in place and found that the level of Risk that results is no greater than similar communities in the area and generally better than projects constructed prior to the current Regulations. The Project Site has two primary egress points, and up to five EVA's which are available for evacuation efforts should law enforcement deem it necessary. Additionally, the combination of fuel modification/defensible space, hardened structures, and the placement of the structures and features on the topography relative to the wildland fuels creates a community that is capable of "sheltering in place" if necessary. While never a first choice by emergency service providers, if moving the population is a greater risk, this community, as designed and as it will be constructed, is capable of a sheltering operation without undue risk to the residents.

All fire scenarios that have been modeled have multiple Evac Points which are viable for specific periods of time. It should be noted that by the time the reaches the downwind evacuation point, the earlier evacuation points may become available for use by traveling through the center of the development area. All of the fire scenarios are run under extreme conditions which have not been recorded in previous fires or which are not likely to occur in the future; they are worst-case scenarios.

Evacuation reduces exposure to pollutant concentrations generated by wildfire. The combined effects of the fuel modification/defensible space, roadside clearance, wildland fire building code requirements, and the design/placement of the structures on the topography work together to protect the community from wildfire. The Project Site will, in fact, provide a buffer to some of the existing communities by removing or modifying the wildland fuels which are upwind from them. With the fuel modification/defensible space and roadside clearance in place, the probability of a fire originating from the Project Site is lower than the adjacent communities without this level of protection. In order to access the wildlands, it will be necessary to traverse either the 100' fuel modification/defensible space zone or the roadside clearance zone. Ignitions from the normal sources associated with development will be much less likely to occur.

As proposed, the Project Site will have a less than significant impact on wildfire risks, project occupants would not be exposed to pollutant concentrations from a wildfire or the uncontrolled spread of a wildfire as in most cases, as they will be able to evacuate.

3. Determine if the installation or maintenance of associated infrastructure (such as roads, fuel breaks, emergency water sources, power lines or other utilities) may exacerbate fire risk, or that may result in temporary or ongoing impacts to the environment;

All of the improvements for the Project Site have been identified and analyzed for their impact on the environment in the CEQA process. None of the Project Site infrastructure will exacerbate the fire risk for the Project Site. In fact, the improved water supply for the general area, the placement of fuel modification/defensible space zones and the

establishment of a community that has the option to “shelter in place” if needed provides an alternative to the existing residents where this level of protection does not exist. If evacuation is not possible from the region, nearby communities would be safer traveling to the Project Site development areas than they would be in some of the current neighborhoods due to the added protections provided in the Project Site.

As proposed, the Project Site will have a less than significant impact on ongoing impacts to or exacerbation of the environment as a result of installation or maintenance of associated infrastructure related to wildland fire risk.

4. Determine if people or structures will be exposed to significant risks due to the completion of the project; and

The required wildland fire protection features, and the additional protection measured identified in this report, will keep the residents and the structure of the Project Site protected from significant risk by the required Regulations and the manner in which the Project Site will be developed (clustered development with a definable interface vs an intermix community). The risk from wildland fires for the Project Site will be less than the surrounding communities as the Regulations under which the project will be developed have significantly increased the level of protection required as a baseline for development projects. Coupled with the additional protection measures listed in this report, the Project Site has mitigated the hazards in the adjacent native vegetation to an acceptable level of risk under current Regulations.

As proposed, the Project Site will have a less than significant impact on increasing or creating new risk associated with completion of the project. A strong case can be made that the Project Site reduces risk to the existing communities by providing a buffer between the fire and the existing communities. The Project Site will be constructed to current standards and is not expected to allow fire to move into the existing communities which are downwind with the same level of intensity and rate of spread.

5. Consider whether a project will “expose people or structures, either directly or indirectly, to a significant risk of loss, injury or death involving wildland fires.”

As proposed, the Project Site will not expose people or structures, either directly or indirectly, to a significant risk of loss, injury or death due to a wildland fire in the native areas adjacent to the Project Site due to the use of Fuel modification/defensible space, Defensible Space, Fire Sprinklers, placement of the structure on the Landscape/Topography, the width of the streets, the amount of fire protection water available and the placement of the fire hydrants are specified intervals, the hardening of the structures to comply with the current wildland interface Regulations and availability of firefighter resources within the Project Site and the regional assets available to combat a wildland fire by the Fire Department and the other associated agencies (CalFire, USFS, mutual aid fire resources, Call when needed fire resources) who routinely assist in the suppression of wildland fire in the region.

As proposed, the Project Site will have a less than significant impact on creating or increasing the exposure of people or structures, either directly or indirectly, to a significant risk of loss, injury or death involving wildland fires. The Project Site will be significantly more protected than the existing communities which were not constructed to the current standards and do not have the same protections afforded the Project Site through its system's approach to wildland fire defense.

Conclusions and Recommendations

A review of the expected fire behavior in the interface of the Marble Valley development indicates that the fire behavior could produce extreme fire behavior, and as such, risk reduction measures will be necessary. Many of these risk reduction measures are required by the State and Local fire/building regulations, fire department standards, and guidelines, and by risk reduction measures already considered and applied by the development review process. Fire behavior modeling predicts that there will be varied timeframes for evacuation of the Project Site under fire scenarios where the fire is burning into the community from an adjacent area. Each scenario has its own set of parameters. Where fires are initialized within the Project Site or near its boundary, the fire incident command and control may have to determine if the population will be moved or "sheltered in place."

The proposed community with its increased built-in fire protection features (defensible space, fuel modification, hardening of the structures and required maintenance), placement of the structures on the topography, overall orientation to the fuels, wind, and slope and nested (safe center) configuration would be a candidate for a "shelter in place" decision. While "shelter in place" is never a first option, history shows us that moving populations, once the fire has arrived, has increased risk, and should not be attempted when safe alternatives exist.

The configuration of the Project Site, the placement of the structures and features on the topography and the nature of the wildland fuels surrounding the project create conditions where the fire will travel at great speeds when wind, slope and fuel align but all of the access points are not impacted by fire at the same time.

The fire behavior static modeling in this report with flame lengths of up to 55' under the worst-case scenario would be protected by compliance with the Fire Department fuel modification/defensible space standards. Fuel modification/defensible space is designed to reduce and change the fuel types as the combustible vegetation gets closer to the structure. As a "rule of thumb," two times the maximum flame length is adequate protection from radiant heat in a hardened structure. These distances also protect from direct flame contact (a distance greater than the flame length by a factor of two) and convected heat (less impactful than the radiant heat distance as discussed previously). The structure hardening (including ember intrusion projection) protects from embers and brands which may travel long distances under worst-case conditions.

With respect to the defensible space distance for the perimeter structures, the Fire Department requires distances of 100 feet of fuel modification/defensible space based on the adjacent fire potential as measured by the slope, aspect, fuel characteristics, fire history, and weather data

(wind, temperature, and relative humidity). While the distance required in the thinning zones may be allowed to be reduced based on the level of hazard present, the zones nearest the structures are rarely reduced.

Additionally, the implementation of Zone 0 (the first five feet from the structure) will only enhance the already robust level of protection for the Project Site.

It has been determined that, with the implementation of the risk reduction measures set forth in this report, the proposed development areas set forth as project configurations will have a less than significant impact from the wildland fire-related issues raised under the AG Guidelines, as well as under CEQA Guidelines Appendix G, Section XX Wildfire.

Appendix B – Modeling Outputs

B-2 – Scenario Locations/Wind Directions (Access and Evac Points Provided)

B-3 to B-137 – FlamMap/Minimum Travel Time Outputs

B-134 to B-138 – BehavePlus Outputs

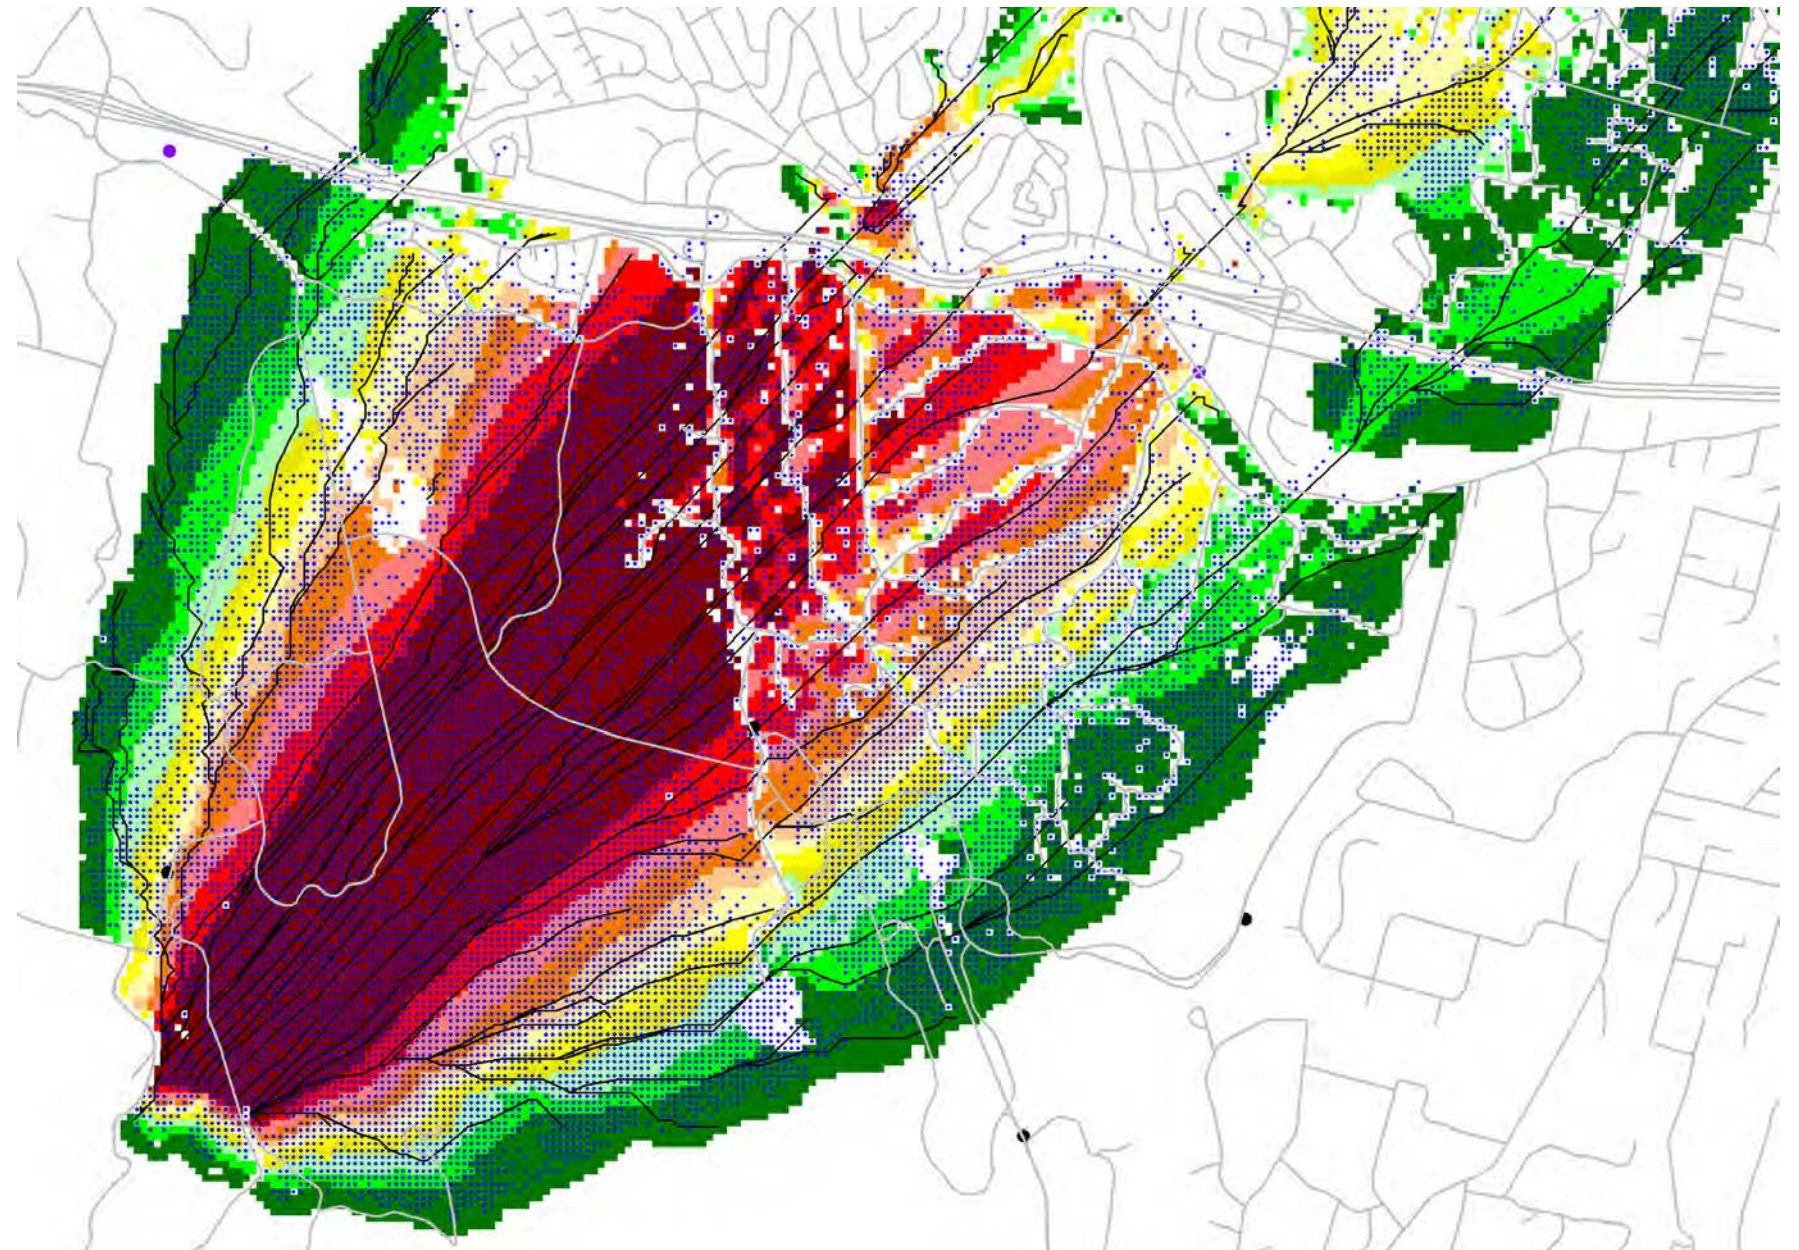

Marble Valley/Lime Rock Developments Fire Behavior Analysis Locations

Modeling Locations

Modeling Assumptions:

1. Moisture Scenario will be 3, 4, 5, 30, 50 (extreme)
2. Wind will be assumed to be from:
 - a. N, NNE, NE at 45 mph
 - b. SE, SSE, S, SSW, SW at 65 mph
3. Fuel models to be used
 - a. LCP_LF2022_FBFM40_220_CONUS
 - b. No modifications have been done to any layers
4. Development area are used as fire barriers due to fuel modification and defensible space protection. Community burn through is not expected.
5. Fire scenario will be with sustained winds (no diurnal effect)
6. No fuel conditioning is used with worst-case moisture scenario
7. Arrival Times are shown to eight hours, but fire scenario is unlimited
8. Foliar Moistures are assumed to be 100
9. Crown Fire Calculation Method is set to Finney (2004)
10. Spotting Probability is set to 0.99
11. Spotting Delay is set to 0
12. Fuels have not been adjusted to any disease or drought impacts
13. Slopes and Aspects have not been adjusted in the development area (barrier file adjusts this to some degree)

Modeling Note: Each of the blue dots on the graphic above is an ember landing location. Since the spotting probability is set to 99%, each of the downwind locations is available. The software will select the spotting locations randomly. Since this will be different on each run of the scenario, minor differences will occur if the same scenario is run multiple times.

Executive Summary

This report presents the results of the wildfire evacuation time analysis conducted for the Village of Marble Valley Specific Plan Project (hereafter referred to as “Marble Valley Specific Plan” or “Project”) to comply with the requirements of the California Environmental Quality Act (CEQA) as established in the CEQA Statute and CEQA Guidelines and applicable/published court decisions.

Purpose

The purpose of this wildfire evacuation assessment is to address CEQA guidance released by the Attorney General in response to recent California Environmental Quality Act (CEQA) court decisions whereby EIRs were deemed to be inadequate due to the lack of a sufficient analysis around the Project's effect on the ability of the local community to evacuate due to a wildfire or similar disaster, and compliance with CalFire regulations related to wildfire evacuation and emergency access.

Project Description

The Project includes the development of 3,236 dwelling units, 87 acres of public facility / recreational use, 475,000 square feet of commercial use, 35 acres for two public schools (K5 / K8), 1,284 acres of open space, 55 acres of agricultural use, and 61 acres of new road impact areas and future right-of-way. Planned improvements are proposed for 1,875 acres of the 2,341-acre site. Most of the development would occur north of Deer Creek. The proposed project expands the Community Region of El Dorado Hills to include the Project area.

US 50 access will be through the US 50 / Bass Lake Road and US 50 / Cambridge Road interchanges. Marble Valley Parkway is proposed as a continuous roadway connecting the Bass Lake Road and Cambridge Road interchanges. A portion of Marble Valley Parkway is outside the plan area. Marble Lake Boulevard, which is planned as a four- to two-lane roadway, will provide the primary access roadway serving the project. Marble Lake Boulevard will be four lanes from US 50 to just south of Marble Valley Parkway. Major intersections along Marble Lake Boulevard are planned to have roundabout control. Lime Rock Valley Boulevard will extend east of Marble Lake Boulevard as a two-lane roadway.

Study Overview

The study uses evacuation time estimates as a metric to evaluate evacuation performance. Evacuation time is defined as the estimated time necessary to safely evacuate all evacuees, from the time when a hazard is first identified until the time when the last evacuee leaves a hazardous area.

The study was conducted in coordination with Firesafe Planning Solutions, emergency service providers, and fire agencies. The evacuation assesses the four development scenarios under existing conditions:

- No Project – Represents existing conditions (i.e., existing residents).
- Marble Valley Specific Plan – Represents existing conditions with buildout of the Marble Valley Specific Plan.
- Lime Rock Valley Specific Plan – Represents existing conditions with buildout of the Lime Rock Valley Specific Plan.
- Marble Valley & Lime Rock Valley Specific Plans – Represents existing conditions with buildout of both the Marble Valley and Lime Rock Valley Specific Plans.

Wildland Fire Evacuation Risk and Fire Behavior Report

Firesafe Planning Solutions prepared a wildland fire risk report for the Village of Marble Valley Specific Plan, *Wildland Fire Evacuation Risk Report, Fire Behavior – The Village of Marble Valley Project* to assess the risk related to wildfires and the intensity of a wildfire approaching the Project site and covers the following topics:

- Current Environmental Conditions – Identifies the location of the project site and adjacent wildland and agency responsible for fire protection.
- Wildland Fire Evacuation Risk and Fire Behavior Report – Analyzes the likelihood and intensity of wildfire hazards and the risk/vulnerability of the project to wildfire hazards.
- Project Impacts Related to Wildland Fires – Analyzes the project design relative to wildfire events and incorporates the fire history of the project area, weather (i.e., temperature, relative humidity, wind), fuel (i.e., wildland and built environment), geography (i.e., slope, aspect, elevation), and historical fire activity.
- Water Supply and Infrastructure – Describes the existing and proposed water supply and infrastructure.
- Fire Protection Resources – Identifies the existing and proposed fire resources.
- Risk Reduction Measures – Outlines risk reduction measures required by code, ordinance, and standards as well as additional benefits that the project provides to existing communities.

The analysis considers existing/future vegetative interface fuels, topography, fire, and weather conditions during extreme fire conditions. The report provides results of computer modeling that measured the fire intensity, flame lengths, rate of spread, and fire travel distance (arrival times) from worst-case scenario wildfires in both the extreme (Diablo wind) and the predominant (Onshore wind) wind conditions.

The results of fire behavior modeling have been incorporated into the analysis of the interfaces of the project with adjacent wildlands and the potential ingress/egress routes used by the Project site daily and under emergency conditions where evacuation might be necessary. **Appendix A** includes the *Wildland Fire Evacuation Risk Report, Fire Behavior – The Village of Marble Valley Project*.

Evacuation Time Estimates

The study uses evacuation time as a metric to evaluate evacuation performance.

As outlined in the *Wildland Evacuation Fire Risk Report, Fire Behavior – The Village of Marble Valley Project*, the fire scenarios modeled are extreme and the results indicate the fire will be traveling at a rate faster than fire suppression activity will allow for control lines. The size, location and configuration of the Project site makes it unlikely that a fire will impact the entire evacuation area, but rather the fire will impact different portions over time. Consequently, evacuation time estimates are developed for the following evacuation conditions:

- Self-Evacuation – Represents the evacuation of populations in the direct path of the fire where advanced notice is not available due to the fire’s progression. These vulnerable populations are in the red areas (i.e., where the fire’s progression is 60 minutes or less) shown in **Figures ES1 through ES4**. As analyzed, evacuation is assumed to begin within 15 minutes of the fire’s recognition. However, self-evacuation may be a part of an Ordered Evacuation, representing an initial phase of the evacuation that occurs before the Sheriff issues an order to evacuate. Evacuation time is estimated from the evacuation trip origin to the closest safe location not in the direct path of the fire, which may be inside or outside the study area shown on **Figure 2**.
- Ordered Evacuation – Represents the evacuation of the entire population (residents, students, employees, and visitors) in the evacuation area for an event with ample notice where emergency services are participating in the evacuation. As analyzed, the evacuation window is 3 hours (180 minutes) beginning from the Sheriff ordering the evacuation. Evacuation time is estimated from the evacuation trip origin to the study area gateways, outside the study area.

Self-Evacuation (Vulnerable Population)

The analysis results for Self-Evacuation are summarized in **Figures ES-1 through ES-4**.

As shown, the addition of the Project slows the progression of the fire event. Consequently, the vulnerable population in the existing community areas will decrease compared to existing conditions due to the fuels removed by the Project, fuels management activities, and the creation of fire breaks conducted around the Project perimeter. Under Fire Scenarios 2 and 4, all the existing community areas would be outside the vulnerable areas with the addition of both the Project and Lime Rock Valley Specific Plans.

For all fire scenarios, it would take less than 20 minutes to move all the vulnerable evacuees (i.e., existing or project evacuees) to a safe location, which is less than the 30 minute fire progression shown in **Figures**

ES1 through ES8. The maximum total time to safety would decrease for existing vulnerable evacuees with the Project. This is due to the increased access to evacuation routes and the slowed progression of the fire created by the removal of fuels and vegetation and fuels management activities occurring with the Project, which creates additional safe areas for vulnerable evacuees to access.

Ordered Evacuation

The analysis results for the Ordered Evacuation are summarized in **Figures ES-5 through ES-8.**

For all fire scenarios, it would take less than 200 minutes to evacuate the study area. For most fire scenarios, the addition of project evacuees would not increase the total time to evacuate existing residents. In most instances this is due to the increase in available evacuation routes (i.e., more routes) and an increase in the availability of evacuation routes (i.e., routes remain viable for evacuation longer), resulting from the slower progression of the fire due to the addition of the project.

Under Scenario 4, the addition of the Project would result in an increase of about 5 minutes in the total evacuation time for existing residents. Under this scenario, the fire location is on the south end of the Project, so the effect of the Project on the progression of the fire is limited because the Project does not remove fuels in the path of the fire. Consequently, the availability of Emergence Vehicle Access (EVA) 2 is reduced to 150 minutes and the Northeast Access (i.e., Durock Road and the US 50/Cameron Park Drive interchange) is reduced to 90 minutes. This reduction in evacuation route availability results in longer travel time for some existing evacuees that must use more distant or more congested access routes. However, as outlined above in the Self-Evacuation analysis, the addition of the Project would decrease the time for existing vulnerable evacuees to move to safety. Therefore, the increase in total evacuation time will not affect the ability to get to a safe location before direct exposure to the fire.

With the addition of the Project and the Lime Rock Valley Specific Plan, the total time to evacuate the existing evacuees would be like no project conditions. Again, this is due to the increased access to evacuation routes and the slowed progression of the fire with the Lime Rock Valley Specific Plan due to the removal of wildland fuels.

The EVAC+¹ results do not include potential unknown factors that could produce much longer travel times such as road closures due to stalled or inoperable vehicles or other blockages such as falling trees.

Cumulative Conditions

The analysis results presented above for existing conditions are applicable to cumulative conditions, since the Project and proposed Lime Rock Specific Plan are the only significant development projects in the study

¹ EVAC+ is a dynamic traffic assignment model, is built in TransCAD 8.0, sensitive to how demand flows in short periods of time affects the speed of travel on the roadway network and the resulting ability of individual roadway segments to accommodate that demand.

area that would add substantial population and transportation facilities that may affect the evacuation routes that may be used by the existing communities.

East Ridge Village is an approved planned residential development between the Project (i.e., to the west) and the existing Blackstone community, east of Latrobe Road. As a planned development, East Ridge Village was not assumed in the evacuation time estimates presented above. In addition, East Ridge Village does not include any full access roadway connections to the Project or to the evacuation routes shown on **Figure 2**.

However, future development of East Ridge Village would affect the behavior of Fire Scenario 16 by reducing the progression of the fire event. **Figure ES-9** shows the progression of Fire Scenario 16 with the addition of the approved East Ridge Village development. As shown, East Ridge Village would substantially delay the progression of the fire event to the point where the fire would take 200 or more minutes to reach the Project and the fire would not burn through the project to existing communities to the east. This is due to the slowed progression of the fire created by the removal of fuels with East Ridge Village.

1. Introduction

This report presents the results of the wildfire evacuation time analysis conducted for the Village of Marble Valley Specific Plan Project (hereafter referred to as “Marble Valley Specific Plan” or “Project”) to comply with the requirements of the California Environmental Quality Act (CEQA), guidance provided by the Attorney General’s office, and applicable/published court decisions.

This chapter describes the purpose of this document, describes the Project, summarizes the fire risk and behavior report that informs the evacuation analysis, outlines guidance from the Attorney General guidance and CalFire Regulations, defines fire hazard severity zones, summarizes consultation with local agency staff, discusses the limitations of the emergency evacuation assessment, and outlines the report organization.

Purpose

The purpose of this wildfire evacuation assessment is to address CEQA guidance released by the Attorney General in response to recent California Environmental Quality Act (CEQA) court decisions whereby EIRs were deemed to be inadequate due to the lack of a sufficient analysis around the Project's effect on the ability of the local community to evacuate due to a wildfire or similar disaster.

Project Description

The Project includes the development of 3,236 dwelling units, 87 acres of public facility / recreational use, 475,000 square feet of commercial use, 35 acres for two public schools (K5 / K8), 1,284 acres of open space, 55 acres of agricultural use, and 61 acres of new road impact areas and future right-of-way. Planned improvements are proposed for 1,875 acres of the 2,341-acre site. Most of the development would occur north of Deer Creek. The proposed project expands the Community Region of El Dorado Hills to include the Project area.

US 50 access will be through the US 50 / Bass Lake Road and US 50 / Cambridge Road interchanges. Marble Valley Parkway is proposed as a continuous roadway connecting the Bass Lake Road and Cambridge Road interchanges. A portion of Marble Valley Parkway is outside the plan area. Marble Lake Boulevard, which is planned as a four- to two-lane roadway, will provide the primary access roadway serving the project. Marble Lake Boulevard will be four lanes from US 50 to just south of Marble Valley Parkway. Major intersections along Marble Lake Boulevard are planned to have roundabout control. Lime Rock Valley Boulevard will extend east of Marble Lake Boulevard as a two-lane roadway. **Figure 1** shows the Project and backbone roadway network.

Wildland Evacuation Fire Risk and Behavior Report

Firesafe Planning Solutions prepared a wildland fire risk report for the Village of Marble Valley Specific Plan, *Wildland Fire Evacuation Risk Report, Fire Behavior – The Village of Marble Valley Project*, to assess the risk related to wildfires and the intensity of a wildfire approaching the Project site and covers the following topics:

- Current Environmental Conditions – Identifies the location of the project site and adjacent wildland and agencies responsible for fire protection. The fire risk and behavior report presents the existing vegetation on and near the Project beginning on Page 9.
- Wildfire Hazard and Risk Analysis – Analyzes the likelihood and intensity of wildfire hazards and the risk/vulnerability of the project to wildfire hazards. The fire risk and behavior report discusses the wildland fuels on and near the Project beginning on Page 29.
- Project Impacts Related to Wildland Fires – Analyzes the project design relative to wildfire events and incorporates the fire history of the project area, weather (i.e., temperature, relative humidity, wind), fuel (i.e., wildland and built environment), geography (i.e., slope, aspect, elevation), vegetation and fuels management included in the proposed Project, and historical fire activity. The fire risk and behavior report discusses the effect of the Project on wildland fire behavior beginning on Page 50.
- Water Supply and Infrastructure – Describes the existing and proposed water supply and infrastructure, beginning on Page 69.
- Fire Protection Resources – Identifies the existing and proposed fire protection resources available to serve the proposed Project, beginning on Page 72..
- Risk Reduction Measures – Outlines risk reduction measures required by code, ordinance, and standards as well as additional elements of the proposed Project that reduce wildfire risk for the Project site and existing communities. This discussion begins on Page 78.

This wildland fire risk report provides the results of that assessment and objective hazard and risk assessments that can be used to establish the community risk reduction measures (hazard less reduction measures = risk) that are equal to or greater than the hazards that would be encountered in a worst-case scenario. The analysis considers existing/future vegetative interface fuels, topography, fire, and weather conditions during extreme fire conditions. The report provides results of computer modeling that measured the fire intensity, flame lengths, rate of spread, and fire travel distance (arrival times) from worst-case scenario wildfires in both the extreme (Diablo wind) and the predominant (Onshore wind) wind conditions.

The results of fire behavior modeling have been incorporated into the analysis of the interfaces of the project with adjacent wildlands and the potential ingress/egress routes used by the Project site daily and

under emergency conditions where evacuation might be necessary. **Appendix A** includes the *Wildland Fire Evacuation Risk Report, Fire Behavior – The Village of Marble Valley Project*.

Attorney General Guidance

On October 10, 2022, the Attorney General's office published *Best Practices for Analyzing and Mitigating Wildfire Impacts of Development Projects Under the California Environmental Quality Act* (AG Guidance). The AG Guidance is designed to help lead agencies comply with CEQA when considering whether to approve projects in wildfire-prone areas. The guidance provides "*suggestions for how best to comply with CEQA when analyzing and mitigating a proposed project's impacts on wildfire ignition risk, emergency access, and evacuation.*"

The AG Guidance describes CEQA's requirements in the following two analysis categories.

- Analyzing Impact on Wildfire Risk
- Analyzing Impact on Evacuation & Emergency Access

Section IV.B of the AG guidance outlines variables that should be considered in the analysis of impact on wildfire risk related to the following project characteristics.

- Project Density
- Project Location in the Landscape
- Water Supply and Infrastructure

This information is included in the fire risk and behavior report.

Section IV.C of the AG Guidance contains the following recommendations regarding evacuation and emergency access. Specifically, evacuation modeling and analysis should include the following:

- Evaluation of the capacity of roadways to accommodate project and community evacuation and simultaneous emergency access.
- Assessment of the timing for evacuation.
- Identification of alternative plans for evacuation depending upon the location and dynamics of the emergency.
- Evaluation of the project's impact on existing evacuation plans.
- Consideration of the adequacy of emergency access, including the project's proximity to existing fire services and the capacity of existing services.

- Traffic modeling to quantify evacuation time estimates under various likely scenarios.

The evacuation analysis contained in this report addresses the recommendations in Section IV.C of the AG Guidance.

CalFire Regulation Compliance

The El Dorado Hills Fire Department is the current service provider on the west side of the Project and the El Dorado County Fire Protection District is the current service provider to the east side of the Project.

If approved, the LAFCO will examine the current boundaries and adjust them to provide for the “natural service provider” based on each agency’s ability to provide the services to the new areas. The Project Site includes a fire station site, which may be a relocation of Fire Station 92 (Ryan Ranch) that is currently unstaffed. **Appendix A** includes the *Wildland Fire Evacuation Risk Report, Fire Behavior – The Village of Marble Valley Project*, provides additional discussion of fire protection resources.

Overall wildland fire jurisdiction is classified as FRA (Federal Responsibility Area), SRA (State Responsibility Area) or LRA (Local Responsibility Area). FRA is federal land, (i.e., a national forest). SRA is land with the State of California that the state has the primary responsibility for wildland fire protection. CalFire provides that service for SRA in El Dorado County. LRA is land within incorporated cities and unincorporated land within the county that does not meet the criteria for inclusion in the SRA (i.e., normally developed to a density that makes it urban).

The Project is located on lands designated as a State Responsibility Area (SRA), where CalFire is the primary emergency response agency responsible for wildland fire protection. As a result, the Project must comply with state requirements for wildfire protection and safety, as reviewed and approved by CalFire. These state requirements include State Minimum Fire Safe Regulations, California Building and Residential Codes (Materials and Construction Methods for Exterior Wildfire Exposure), and California Fire Code Chapter 49 (Requirements for Wildland-Urban Interface Areas).

Fire Hazard Severity Zones

Fire Hazard Severity Zones (FHSZ) are currently based on potential fuels, fire weather conditions, and terrain and represent potential fire hazard exposure to structures and other human infrastructure assets. FHSZ areas are adopted as a Title 14 regulation, fulfill the obligations laid out in Public Resources Code (PRC) Sections 4201-04, and are essential in various fire safety regulations, building construction standards, and real estate hazard disclosure requirements. These zones were determined in November 2007 for SRA and September 2008 for LRA and are currently in the process of being revised by CalFire (CalFire Website). The 2007 Fire Severity Zone Map is provided in the Reference section of the *Wildland Fire Evacuation Risk Report, Fire Behavior – The Village of Marble Valley Project*, in **Appendix A**. New “draft” maps are out for review for the SRA areas for the entire state. As proposed in the new maps (November 21, 2022), the Protect site and adjacent lands are classified as Very High and High Fire Hazard

Severity Zones. Adoption of the new maps is anticipated in 2024. Changes (due to the comment period) are not expected for the Project site.

Local Agency Consultation

The following emergency service providers and agency staff were consulted during the preparation of the fire behavior analysis and the evacuation assessment:

- El Dorado Hills Fire Department – Fire Chief, Maurice Johnson and Division Chief/Fire Marshal, Chrishana Fields.
- El Dorado County Fire Protection District – Fire Chief, Tim Cordero.
- El Dorado County Office of Emergency Services (OES) – Sergeant, Leslie Schlag.
- CalFire (Amador/El Dorado Unit) – Battalion Chief Wildfire Resiliency Program, Jeff Hoag.
- El Dorado County Department of Transportation – Supervising Civil Engineer, Adam Bane and Senior, Civil Engineer Dave Spiegelberg.

On November 10, 2022, a coordination meeting was held to review the input assumptions to the fire behavior analysis, including existing/future vegetative interface fuels, topography, fire, weather conditions, evacuation routes (primary routes and emergency vehicle access), and the evacuation area. The input assumptions and feedback received during this coordination meeting were incorporated in the analysis presented in the *Wildland Fire Evacuation Risk Report, Fire Behavior – The Village of Marble Valley Project (Appendix A)*, and the evacuation time estimates presented in this report.

In February 2023, coordination with El Dorado County Department of Transportation (DOT) was initiated to identify input parameters for the evacuation time estimates assessments. These parameters included identification of appropriate fire scenarios, time period for evacuation analysis, evacuation area, evacuation routes, data on recent evacuation events, and availability of fire protection and evacuation plans. DOT delegated input on these parameters to the emergency providers (e.g., Fire Departments and County OES). Email correspondence on February 23, 2023.

Coordination with El Dorado County Office of Emergency Services (Sergeant Leslie Schlag) included a coordination meeting on April 19, 2023, to discuss post evacuation experience to support the evacuation time estimates, including the various stages of evacuation and the time required for evacuations. Email correspondence on June 7, 2023, confirmed Tahoe Basin and South Lake Tahoe evacuation performance during the Caldor Fire. Key input relevant to the evacuation time estimate assessment included the duration of the evacuations in the Tahoe Basin during the Caldor Fire. The evacuation of the Tahoe Basin was planned and conducted in stages. The evacuation of the entire Tahoe Basin took about 10 hours, and the staged evacuation of the City of South Lake Tahoe took approximately three hours, with over two and a half hours of stop-and-go conditions.

In addition to local agency consultation, a survey of first responders and emergency service professionals that had participated in the Camp Fire (Butte County) response or currently work in the region was circulated to gather travel time estimates on Skyway (i.e., the primary evacuation route serving the City of Paradise) between the City of Paradise and the City of Chico during the Camp Fire. A key finding of this survey, relevant to the evacuation time estimate assessment, was the duration of the evacuation. Based on the responses, during the Camp Fire, roughly 30,000 to 50,000 people evacuated, and first responders observed two to five hour evacuation times for evacuees on Skyway to get from Neal Road in the City of Paradise to Bruce Road in the City of Chico. Full survey responses can be found in **Appendix B**.

Disclaimer – Limitations of Emergency Evacuation Assessment

Emergency evacuations can occur due to a variety of events. Any emergency movement involves some uncertainty because individual behavior depends on personal risk assessment for the specific type of emergency event and associated evacuation instructions that will be specific to the context of that event. As such, this assessment is intended to provide a broad understanding of the travel time expectations during an evacuation scenario and what effect the Marble Valley Specific Plan project will have on those times. The analysis does not provide a guarantee that evacuations will follow modeling that is used for analysis purposes, nor does it guarantee that the findings are applicable to any or all situations. The analysis will isolate the general effect of the project on evacuation travel times.

Moreover, as emergency evacuation assessment is an emerging field, there is no established standard methodology and there is no established standard for the appropriate length of time to evacuate an area. Fehr & Peers has adopted existing methodologies in transportation planning that, in our knowledge and experience, we believe are the most appropriate. Nevertheless, such methodologies are necessarily also limited by the tools and data available, and by current knowledge and state of the practice.

This assessment is intended to help the county better understand the project's effect on evacuation travel time. As such, the results are based on a set of scenarios and modeling. Fehr & Peers cannot and does not guarantee the efficacy of the analysis beyond a general assessment of the project's effect on evacuation travel time. Any other use of the information would be beyond our professional duty and capability given the uncertainty of evacuation events and analysis limitations noted above.

Report Organization

The following chapters are included in this report to address the Attorney General's guidelines for evaluating evacuation impacts of the proposed Project:

Chapter 1 – Introduction includes the purpose of this document, Project description, consultation with local agency staff, discusses the limitations of the emergency evacuation assessment, and outlines the report organization.

Chapter 2 – Evacuation Scenarios describes the evacuation scenarios used to analyze the evacuation time of the Project and the Project's effect on the ability of the local community to evacuate due to a wildfire or similar disaster.

Chapter 3 – Methodology describes the evacuation time methodology, including the evacuation area and evacuation routes, the evacuation model, and evacuation vehicle trip demand.

Chapter 4 – Evacuation Time Estimates describes the evacuation time results for various evacuation scenarios.

2. Evacuation Scenarios

This chapter presents the study area and evacuation scenarios used for the evacuation assessment.

Fehr & Peers, in coordination with Firesafe Planning Solutions, emergency service providers, and fire agencies identified study area and evacuation routes for analysis, which are shown on **Figure 2**.

The evacuation assessment includes the following four development scenarios:

- No Project – Represents existing conditions (i.e., existing residents).
- Marble Valley Specific Plan – Represents existing conditions with buildout of the Marble Valley Specific Plan.
- Lime Rock Valley Specific Plan – Represents existing conditions with buildout of the Lime Rock Valley Specific Plan.
- Marble Valley & Lime Rock Valley Specific Plans – Represents existing conditions with buildout of both the Marble Valley and Lime Rock Valley Specific Plans.

Study Area

The study area, which was developed through consultation with emergency service providers and agency staff as outlined above, includes the area generally bounded by US 50, Latrobe Road, and South Shingle Road. Labeled as evacuation corridors, these facilities represent the destination for evacuees when considering the evacuation of the entire study area. The shaded parcels in **Figure 2** represent the area that would potentially be evacuating simultaneously with the Project evacuees and may be using the same routes to exit the evacuation area. Actual evacuation areas will depend on the origin and behavior characteristics of the fire event and the evacuation order issued in response to the event.

Evacuation Routes

As shown in **Figure 2**, the Project site includes two general use access points that will be used daily for ingress and egress that will connect to US 50 at the Bass Lake Road and Cambridge Road interchanges. Five EVA (Emergency Vehicle Access) points are identified, with two primarily serving the Marble Valley site and three primarily serving the Lime Rock site, but all of which could be used by either project. The five EVAs are identified below:

- EVA 1 – Connection to Diablo Trail/Marble Ridge Road under existing conditions with a potential future connection to the approved East Ridge Village project.
- EVA 2 – Connection to Deer Creek Road (gate controlled neighborhood).
- EVA 3 – Connection to China Diggins Road/Ryan Ranch Road.

- EVA 4 – Connection to Amber Fields Drive (gate controlled neighborhood).
- EVA 5 – Connection to Shingle Lime Mine Road.

The evacuation analysis assumes that all five EVAs outlined above are available for evacuation with the use of an EVA depending on the specific fire scenario being analyzed.

Additional future EVAs would be provided through the approved East Ridge Village project that would provide access to Latrobe Road and to Valley View Parkway. The future EVAs would also be available to the East Ridge Village and Blackstone communities for evacuation (i.e., to the east) and access by emergency responders.

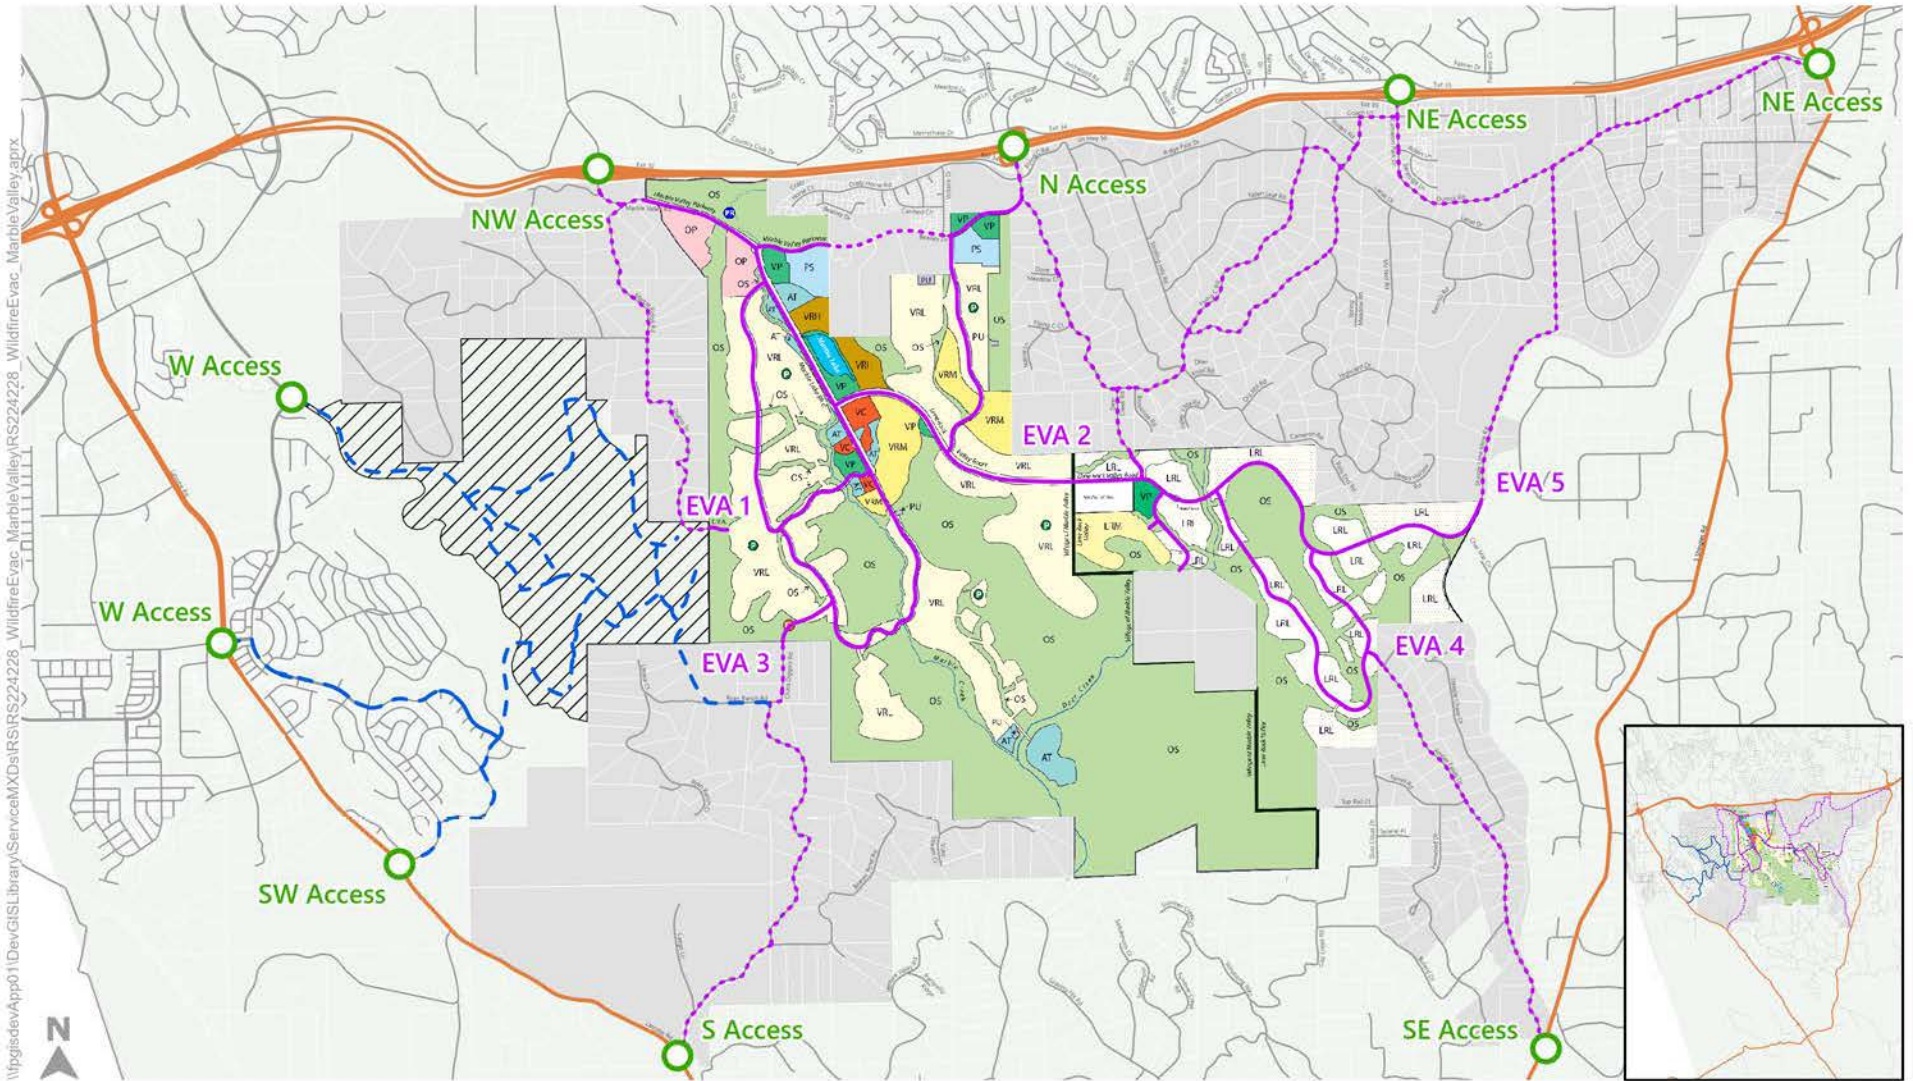

All EVA roadways will be required to meet Public Resources Code (PRC) Section 4290 requirements (e.g., road width, compaction rating, slope, surface material, gates, etc.), which may require off-site improvements to bring existing roadways up to standard.

Evacuation Window

The evacuation time window is the time between when the evacuation order is received, and the time evacuees must begin their evacuation. This does not represent the total time required to evacuate the study area as the total time needed for evacuation will be longer due to distance traveled to exit the evacuation area and congestion.

For this study, a 3-hour evacuation window (i.e., 180 minutes) is used based on the input received from El Dorado County Office of Emergency Services (Sergeant Leslie Schlag), regarding the time to evacuate the City of South Lake Tahoe during the Caldor Fire, and the survey of first responders and emergency service professionals that participated in the Camp Fire in Butte County.

The evacuation window does not apply to self-evacuation, which represents the evacuation of populations in the direct path of the fire where advanced notice is not available due to the fire's progression.

* Evacuation area shown are "potential" areas. Actual evacuation areas will depend on the origin and behavior characteristics of the fire event and the evacuation order issues in response to the event.

Study Area and Evacuation Routes

Study Fire Scenarios

Firesafe Planning Solutions conducted fire behavior modeling for 16 locations surrounding the study area and included different wind direction and speed assumptions, resulting in a total of 33 fire scenarios. Each scenario also includes analysis for no project, with Marble Valley, with Lime Rock Valley, and with Both projects resulting in a total of 132 scenarios. **Figure 3** shows the fire behavior modeling locations. Please refer to **Appendix A**, which includes the *Wildland Fire Evacuation Risk Report, Fire Behavior – The Village of Marble Valley Project*, which summarizes the detailed results of the fire behavior modeling for the 132 scenarios. Each scenario includes how long it will take the fire to reach each evacuation route and the routes that will not be available during a fire scenario.

Fehr & Peers screened all the fire scenarios developed by Firesafe Planning Solutions to identify a worst case set of fire scenarios to use for the evacuation time estimates. The screening considered the availability of evacuation routes and affected area under existing (i.e., no Project) conditions and existing condition with the addition of the Project. Based on this screening, the fire scenarios developed from Locations 2, 4, 7, and 16, shown on **Figure 3**, were selected for the evacuation time estimate assessment. These four scenarios were selected because they would produce the fewest routes available for evacuation for the shortest amount of time. The evacuation performance of the other fire scenarios would be similar to or better than these scenarios. Therefore, detailed analysis is not necessary and their performance can be inferred using the results of the worst case fire scenarios. **Figures 4 through 7** show the progression of each fire event over time for Fire Scenarios 2, 4, 7, and 16, respectively, for the following analysis conditions:

- No Project – Represents existing conditions (i.e., existing residents).
- Marble Valley Specific Plan – Represents existing conditions with buildout of the Marble Valley Specific Plan.
- Lime Rock Valley Specific Plan – Represents existing conditions with buildout of the Lime Rock Valley Specific Plan.
- Marble Valley & Lime Rock Valley Specific Plans – Represents existing conditions with buildout of both the Marble Valley and Lime Rock Valley Specific Plans.

Table 1 summarizes the fire analysis scenarios, including the fire origin, the wind direction, and wind speed. For each fire scenario, **Table 1** summarizes the availability of each evacuation route and the time the route is available for evacuation. Each evacuation route is categorized as follows:

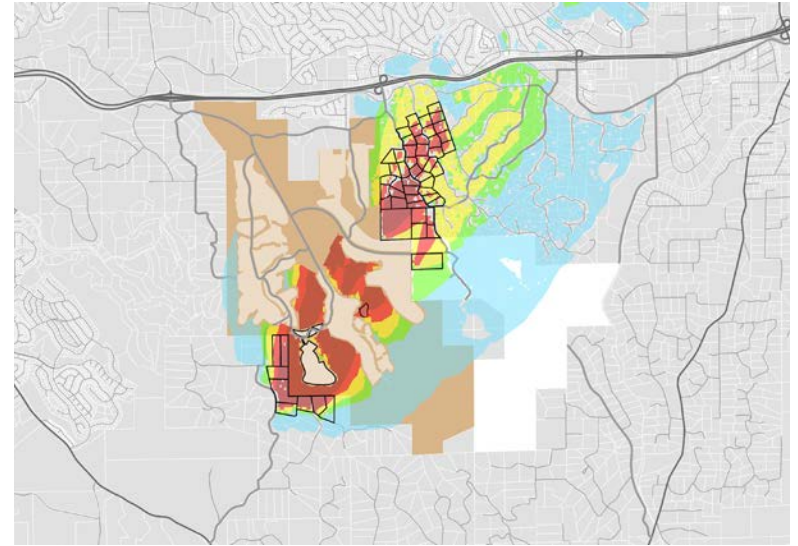

- Available Routes: Evacuation routes available for more than 180 minutes.
- Partially Available Routes: Evacuation routes available less than 180 minutes but more than 30 minutes. For these routes, the time the route will remain available is identified.
- Not Available Routes: Evacuation routes available for 30 minutes or less.

The scenario numbers and names are consistent with the fire behavior modeling scenarios conducted by Firesafe Planning Solutions.

3. Methodology

Forecasting evacuation travel times relies on similar methodology to what is used in conventional travel demand forecasting and traffic operations analysis albeit with modifications to account for the unique circumstances of an evacuation event. The basic steps involve forecasting the demand across specific time periods, determining the distribution of associated trips, assigning the trips to specific routes, and analyzing the capacity of the routes to accommodate those trips. Since evacuation events can generate substantial demand in a brief time, the ability of the roadway network under typical operations can be challenged to accommodate that demand without causing substantial delays such as those reported during the Caldor Fire. Delays experienced would be characterized by forced flow, stop-and-go conditions, and extensive vehicle queuing. With ample notice, an evacuation event could occur with minimal impact to roadway traffic operations and usual travel times. For this study, a short evacuation window is analyzed to isolate the project's effect on evacuation travel times during more severe conditions.

The emergency evacuation time estimates include the following steps:

- Preparing the sub-area network representing the study area and the associated background trips (some background travel demand occurs on portions of the network from people traveling for common activities and not affected by the evacuation).
- Forecasting evacuation vehicle trips during the wildfire event.
- Dynamically assigning trips to the sub-area network.

EVAC+ Model

The Fehr & Peers EVAC+ model has been applied for numerous evacuation time estimates for projects throughout California and was utilized to evaluate the estimated travel time for the four fire scenarios outlined in Chapter 2. EVAC+ uses inputs from the El Dorado County Travel Demand Model for a typical weekday and modifies the travel demand and transportation network to represent the evacuation condition. EVAC+ is built in TransCAD 8.0 and is a dynamic traffic assignment model sensitive to how demand flows in short periods of time affects the speed of travel on the roadway network and the resulting ability of individual roadway segments and intersections to accommodate that demand. After determining the evacuation travel demand and associated transportation network, a dynamic traffic assignment with 15-minute intervals is used to capture the demand and capacity relationship that produces resulting travel speeds and evacuation travel times. Note that this model does not include estimating the time people need to prepare for the evacuation.

Trips were assigned using the EVAC+ tool. The EVAC+ tool relies on the Study Area traffic analysis zones and existing roadway network extracted from the El Dorado County model. Areas affected by the

evacuation event are then processed through the EVAC+ tool trip estimator to estimate the number and sequencing of trips that occur due to the event.

The sub-area extracted network and new trip tables are then input into a dynamic traffic assignment model. A dynamic traffic assignment model estimates traffic and levels of congestion on 15-minute intervals and, as link demand builds (i.e., roads fill with cars), it dynamically reassigns traffic to less congested routes. This is a more accurate way of estimating trip assignment and identifying congested locations on the network that should be considered during an evacuation event. The EVAC+ tool processes are outlined in **Figure 8 and Figure 9**.

Figure 8: EVAC+ Model Framework

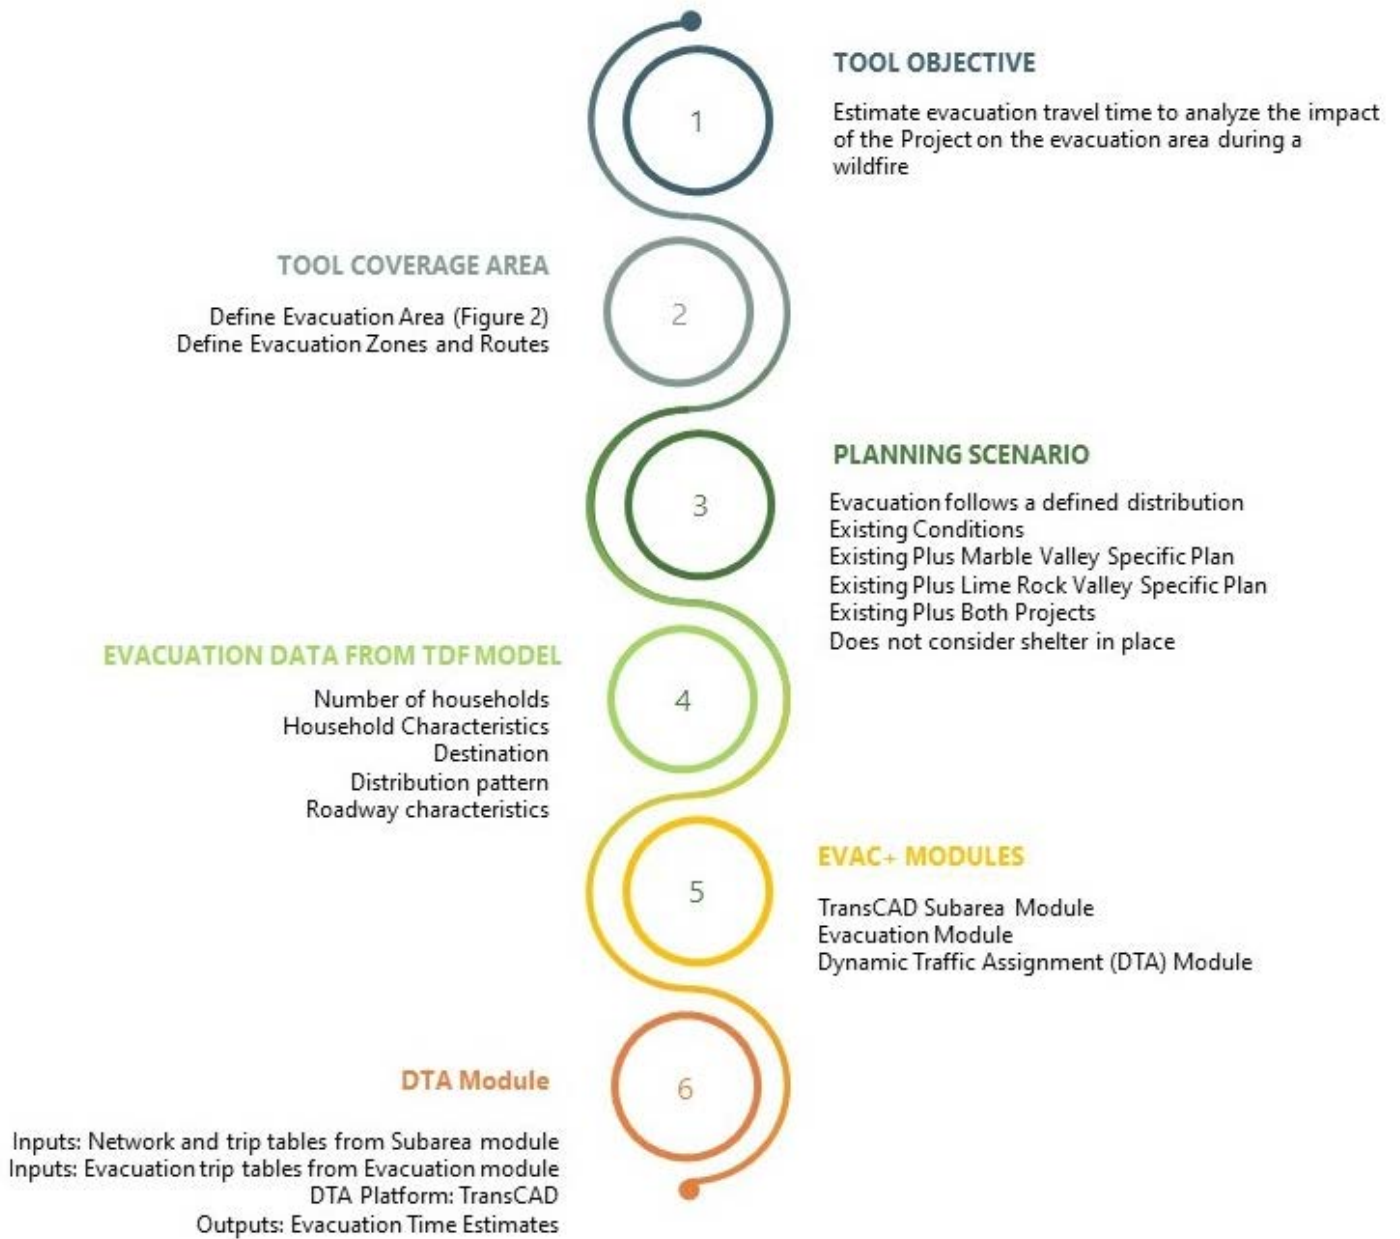

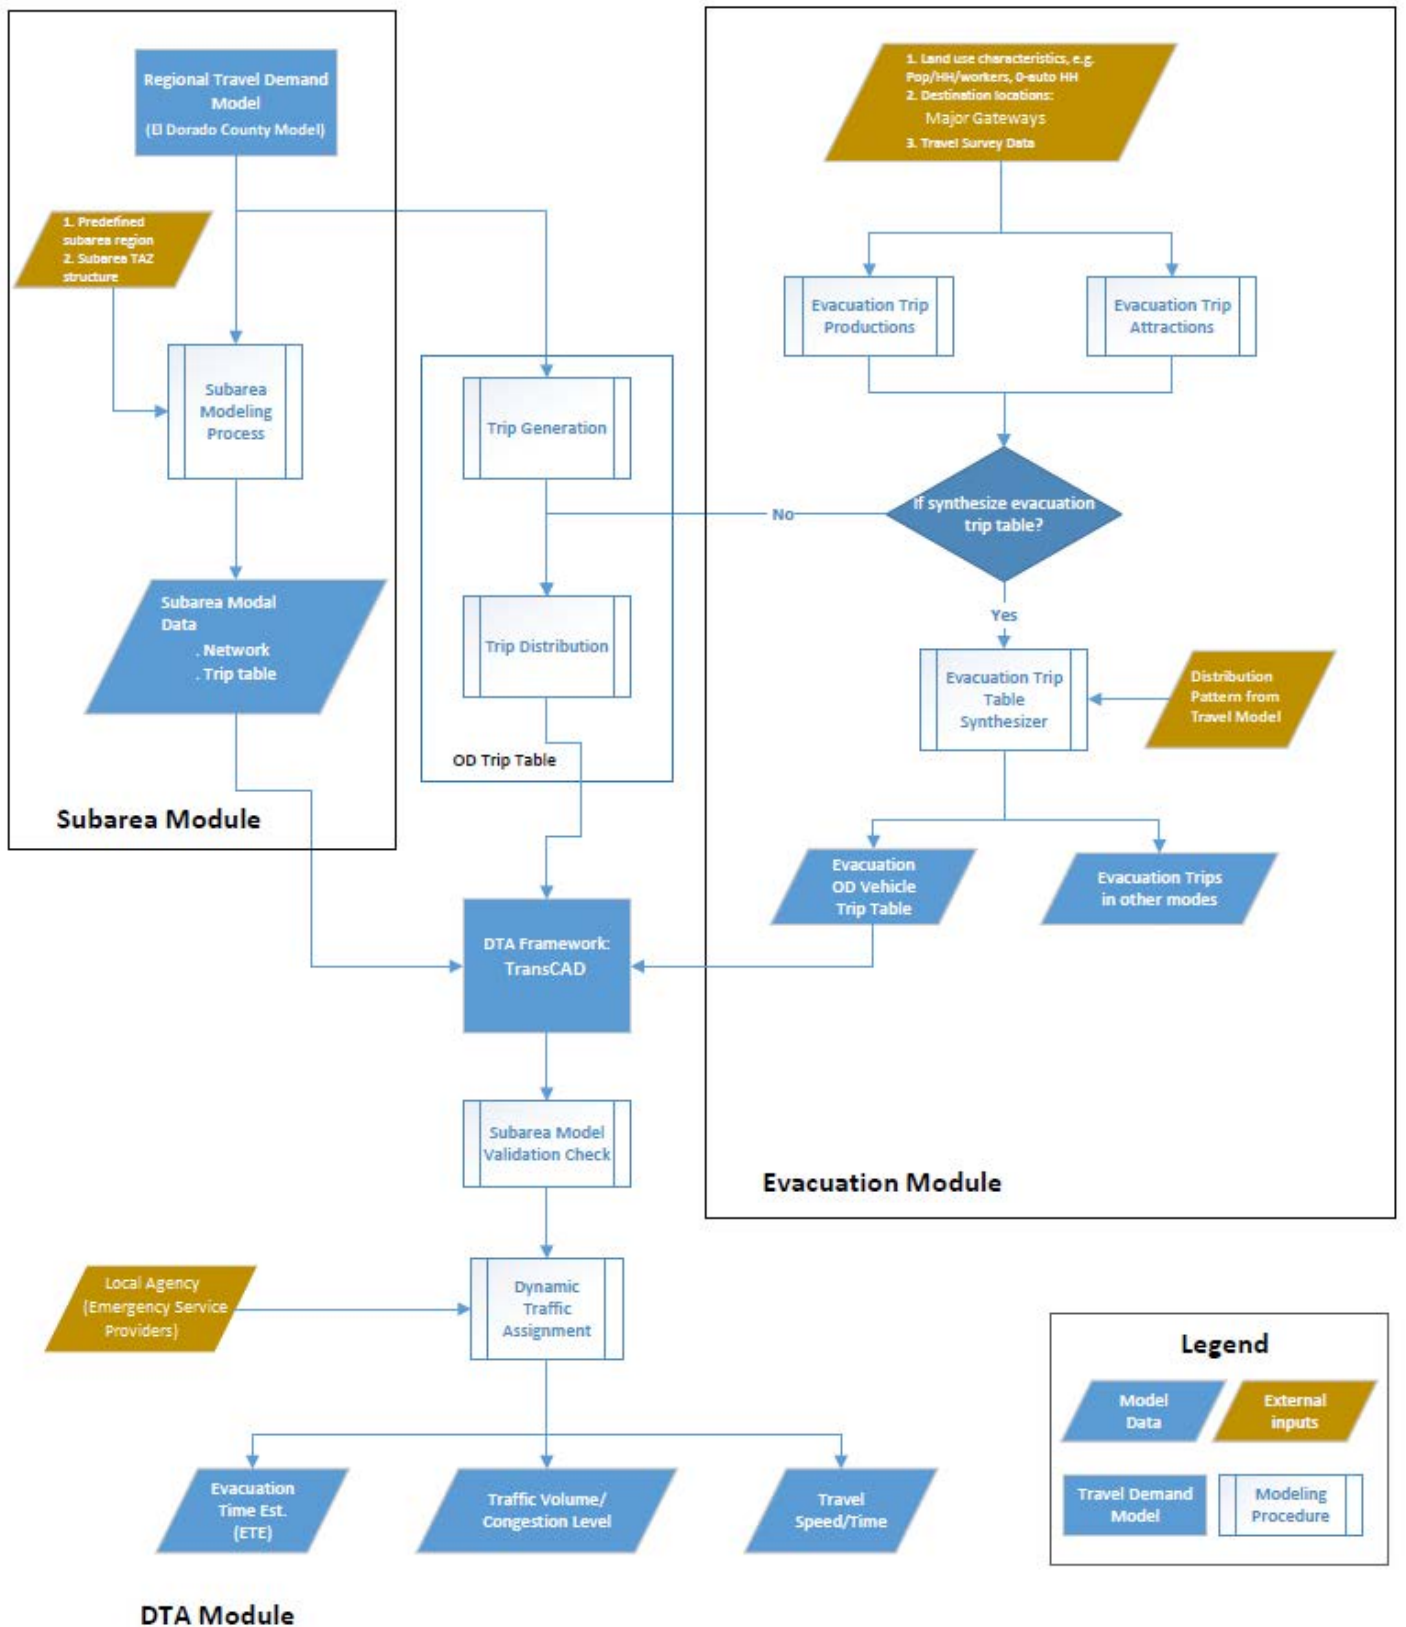

Figure 9: EVAC+ Dynamic Traffic Assignment (DTA) Module

Model Inputs

The travel demand considers the number of people and automobiles used by those evacuating, the background vehicle traffic, and the type of activities being conducted based on the type and timing of the evacuation event. The dynamic traffic assignment model only reflects personal vehicle traffic. Due to the nature of this model, travel made by those in public transit, other shared modes (i.e., vanpool), or walking/biking are not analyzed. The overall vehicle travel demand was based on the typical travel for each hour of daily activity until the evacuation notice was given. The travel demand for evacuation zones was separated from background traffic not associated with evacuation zones.

The inputs to the EVAC+ model are discussed below and include the transportation network, background and evacuation trip matrix, evacuation window, and distribution.

Model Network

EVAC+ includes a transportation network to represent the evacuation condition. The evacuation sub-area is a subset of the El Dorado County travel demand model. A “sub-area extraction” is performed to develop the sub-area model network.

Background Traffic

Background traffic is associated with trips traveling to or from evacuation zones and is taken directly from the El Dorado County travel model for a typical day, then distributed over each hour of the day. Trips that do not end in evacuation zones go about their normal activity regardless of if the evacuation order has been given. Trips that end in the evacuation zone after the evacuation order is given do not travel and stay in the original zone.

Background traffic in the EVAC+ is added as a matrix that shows trips between origins and destinations within the sub-area. The matrix is converted from hourly traffic to 15-minute bins to run the dynamic traffic assignment. Background trips change based on the time of day.

Evacuation Traffic

Evacuation traffic consists of traffic generated by residents, students, employees, and visitors of the evacuation zones. The EVAC+ model uses the land use and vehicle trip inputs to create a matrix of trips between origins and gateways (i.e., destinations) within the sub-area. The matrix is created based on the evacuation departure time and total vehicle trips. The analysis assumed that 100% of the population evacuates.

As outlined in the *Wildland Fire Evacuation Risk Report, Fire Behavior – The Village of Marble Valley Project (Appendix A)*, the fire scenarios modeled are extreme and the results indicate the fire will be traveling at a rate faster than fire suppression activity will allow for control lines. The size, location and configuration of the Project site makes it unlikely that a fire will impact the entire evacuation area simultaneously

(shown in **Figure 2**), but rather the fire will impact different portions over time. Consequently, evacuation time estimates are developed for the following evacuation conditions:

- Self-Evacuation – Represents the evacuation of populations in the direct path of the fire where advanced notice is not available due to the fire’s progression. These vulnerable populations are in the red areas (i.e., where the fire’s progression is 60 minutes or less) shown in the fire scenario figures (**Figures 4 through 7**). As analyzed, evacuation is assumed to begin within 15 minutes of the fire’s recognition. However, self-evacuation may be a part of an Ordered Evacuation, representing an initial phase of the evacuation that occurs before the Sheriff issues an order to evacuate. Evacuation time is estimated from the evacuation trip origin to the closest safe location not in the direct path of the fire, which may be inside or outside the study area shown on **Figure 2**.
- Ordered Evacuation – Represents the evacuation of the entire population (residents, students, employees, and visitors) in the evacuation area for an event with ample notice where emergency services are participating in the evacuation. As analyzed, the evacuation window is 3 hours (180 minutes) beginning from the Sheriff ordering the evacuation. Evacuation time is estimated from the evacuation trip origin to the study area gateways identified on **Figure 2**.

Traffic analysis zone geographies were used to represent neighborhoods and estimate the number of trips for households, employees, students, and visitors. Vehicle trips for evacuation were informed by the existing land use and socio-economic data in each traffic analysis zone. The socio-economic data includes a variety of information based on 2020 5 Year ACS Data Table - B08201, including persons per household, number of employees, auto-ownership information, population, and other factors that could affect the number of vehicles per household used during an evacuation event.

Table 2 summarizes the socio-economic data inputs used to develop the evacuation trips for self-evacuation of vulnerable populations by analysis scenario.

As shown on shown on the fire scenario figures (**Figures 4 through 7**) and summarized in **Table 2**, the addition of the Marble Valley Specific Plan and/or the Lime Rock Valley Specific Plans affect the progression of the fire event. Consequently, the vulnerable population in the existing areas will decrease or remain unchanged.

The change in vulnerable population results from the fuel modification/defensible spaces created by the development, which will be constructed in accordance with the following code, standards, and requirements that are applicable to new development in the Very High Fire Hazard Severity Zones:

- Public Resources Code
- Fire Code
- California Building Code
- California Residential Code

- Fire Department Requirements

Please refer to **Appendix A**, which includes the *Wildland Fire Evacuation Risk Report, Fire Behavior – The Village of Marble Valley Project*, for a comprehensive discussion of fire behavior and the effect of development on fire progression.

Note: Evacuation vehicle trips include evacuation of the entire population (residents, students, employees, and visitors).

Evacuation Distribution

The evacuation time window is the time between when the evacuation order is received, and the time evacuees must begin their evacuation. As discussed in **Chapter 2**, a 3-hour (180 minutes) evacuation window is used for the analysis of the Ordered Evacuation.

Evacuation events are not linear, and it is anticipated that evacuation rate will closely resemble a bell curve from the time that the evacuation order is issued. This is consistent with other research on short-notice evacuation events as documented in the study by Noh et. al² and Florida Hurricane Evacuation³. For this study, curves developed from stated preference surveys of Ashland residents by KLD Engineering were used as a guide. A weighted average distribution was created for all evacuees. **Figure 10** shows the curves from the Ashland survey (i.e., in red, green, and blue) and the curve used for this study (i.e., in yellow).

Table 4 shows the time distribution for each 15-minute time bin. Note that although this is the assumed distribution for the EVAC+ model, emergency scenarios are often unpredictable, and driver behavior can be disorderly.

Depending on the fire event, traffic may be evacuating directly or may be returning home before evacuating, allowing for families to regroup prior to evacuating (i.e., residents with commuters). The

² Noh, Chiu, Zheng, Hickman, and Mirchandani, *Approach to Modeling Demand and Supply for a Short-Notice Evacuation*, Transportation Research Record 2091

³ Roberto Miguel, *Florida Statewide Hurricane Evacuation Model/TIME*, December 9, 2015

number of vehicle trips depends on the type and time of the event, the number of drivers in the household, and the number of vehicles available.

Evacuation Start Time

The start time leaving the evacuation zones varies by type of the event. With different evacuation starting times, the impact of the evacuation trips on the roadway conditions will be different. For example, evacuations occurring at nighttime when all household members are at home will be different from evacuations occurring when all or part of household members have made their regular trips from or to the evacuation areas.

For events where ample notice is given or the family unit is already together, less time is needed to prepare for the evacuation. On the other hand, where little notice of an event or when the family unit is not together, the time required to prepare for an evacuation is typically longer as residents may need to prepare belongings, collect their animals, and conduct other coordination before beginning their evacuation trip.

Evacuation start time for each fire scenario was identified based on the historic wind events used to develop the fire analysis scenarios shown on **Figures 4 through 7**. The fire scenarios were developed based on site-specific wind speeds and directions. Each of the fire scenarios corresponds to historic wind data from weather sites near the study area.

The extreme fire events used in the modeling correspond to "extreme fire weather" or "red flag warning" conditions. Under these conditions, some fraction of the population may complete some preparations for evacuation and be able to evacuate sooner and more efficiently than at other times. However, because it would be speculative to try and estimate the percentage of the population that may make advanced preparations, what those preparations might be, and how they would help expedite the overall evacuation process, this issue is not incorporated into the modelling.

For the evacuation time estimates, the historic wind data was reviewed to identify the time of day the winds for the specific fire scenario occurred. *Wildland Fire Evacuation Risk Report, Fire Behavior – The Village of Marble Valley Project*, includes the detailed analysis of the fire analysis scenarios. **Table 5** shows the evacuation start times for each scenario.

Table 5: Evacuation Start Time Assumptions

Fire Scenario	Wind Direction	Evacuation Start Time
2	SW	11:00 AM
4	SW	11:00 AM
7	SSE	7:00 AM
16	W	1:00 PM

Source: Fehr & Peers, 2023

Evacuation Destination

The destination of evacuating trips depends on whether the evacuation is a Self-Evacuation of vulnerable populations or an Ordered Evacuation. For a Self-Evacuation, the destination is to the closest safe location, which may be inside or outside the study area. For an Ordered Evacuation, the destination is outside the study area using a study area gateway shown on **Figure 2**.

Selectzone model runs were performed to estimate gateway travel for each analysis scenarios. **Table 6** shows the gateway weights or trip attractions for each scenario. The weights are for "Typical Weekday" conditions and vary by analysis scenario. The gateway weights are a starting point for assigning evacuation trips to the study area gateways and adjust through the iterative dynamic traffic assignment process, based on the route availability for each fire scenario as summarized in **Table 1**. The percentages in **Table 6** represent the share of evacuation trips assigned to each study area gateway at the beginning of the evacuation, prior to effect of congestion and rerouting of traffic to less congested routes that occurs with dynamic traffic assignment.

Table 6: Evacuation Gateway Weights

Gateways	Existing	Existing Plus MVSP	Existing Plus LRVSP	Existing Plus MVSP and LRVSP

LRVSP – Lime Rock Valley Specific Plan

Transportation Network Assignment

Depending on the event, the dynamic traffic assignment can model the change in accessibility and use of a roadway over the duration of the event. Some operating conditions that the model can evaluate are described below.

Normal Roadway Conditions

The evacuation time estimate analysis assumes typical daily operating conditions for both the number of travel lanes per direction and associated hourly capacity per lane. This condition allows for the opposite direction of evacuation traffic to be used for emergency responders to access the evacuation area and for background traffic to operate normally.

Contra-Flow Operations

Contra flow operations refer to evacuation travel where traffic is flowing in only one direction (e.g., using both travel lanes of a two-lane roadway for evacuation in the same direction). This condition does not allow for the opposite direction of evacuation traffic to be used for emergency responders to access the evacuation area and prohibits background traffic travel in the opposite direction from the evacuation traffic. The evacuation time estimate analysis does not rely on contra-flow operations.

Capacity Restrictions

The routes that are operational longer than 180 minutes during a fire scenario are assumed to be "Available" for evacuation. The available routes are assumed to be operational at normal capacity.

The roadways that will be operational during a fire scenario for less than 30 minutes are assumed to be “Not Available” for evacuation. These routes are turned off in the dynamic traffic assignment model.

If an evacuation route is available for a specific amount of time that is less than the evacuation window (i.e., 180 minutes), that route is assumed to be “Partially Available” for evacuation. The Partially Available routes are assumed to be turned off after they are not available for evacuation, as specified by the fire behavior analysis. This is indicated in the model by an “incident.” The incident’s start time varies by scenario and is set according to the availability of the routes in **Table 1**. This means that those routes will operate at normal capacity until the fire affects their availability for evacuation. At that point (at incident start time), the route will be closed to evacuation and vehicles rerouted to other evacuation routes/gateways. This will cause additional congestion in the dynamic traffic assignment model.

Model Output

The output for the EVAC+ model includes the following:

- Congested Skim Matrix – Includes matrices of travel time between each zone and gateway for each 15-minute bin (i.e., four per hour) for each hour of the day for a total of 96 matrices.
- Evacuation Vehicle Trip Matrix – Includes matrices of evacuation trips between each zone and gateway for each 15-minute bin that includes evacuation trips. A total of 96 bins are created, but only the time bins within the specified evacuation window are populated.
- Link Flow Network – Includes vehicle volume for each 15-minute bin on the roadway network.

Results from the model are summarized for different population groups to create evacuation time estimate results.

4. Evacuation Time Estimate Results

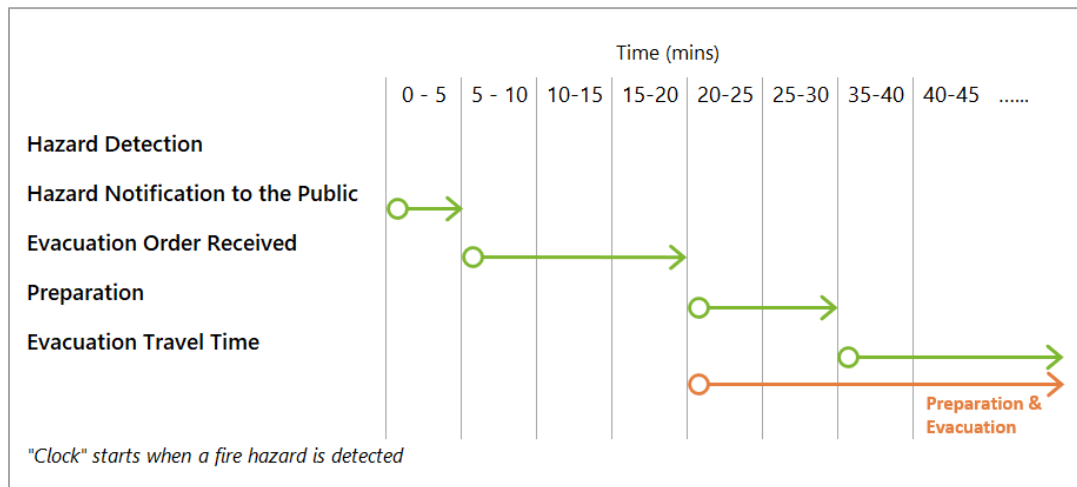

An evacuation time estimate is a metric that is defined as the estimated time necessary to safely evacuate all evacuees, from the time when a hazard is first identified until the time when either the last evacuee leaves a hazardous area, or the remaining population is forced to shelter-in-place. The determination of whether it is the last evacuee or forced shelter-in-place is made by emergency response personnel, is hazard-specific, and considers factors such as the type of hazard or threat, level of notice, population characteristics of the area at the time of the hazardous event, and evacuee behavior. There are several phases of an evacuation time estimate described below:

- Hazard Detection – Time when hazard is first identified.
- Hazard Notification to the Public – Time when any official releases an evacuation order to the public.
- Evacuation Order Received – Time when people receive the evacuation order.
- Preparation – Time it takes to prepare to depart after receiving evacuation order.
- Self-Evacuation Time (Vulnerable Population) – The total elapsed time until all vehicles are out of harm's way, including time driving (moving) and delay due to congestion. The calculated evacuation time is estimated from the evacuation trip origin to the closest safe location not in the direct path of the fire, which may be inside or outside the study area shown on **Figure 2**.
- Ordered Evacuation Time – The total elapsed time until all vehicles are out of the Evacuation Area including time driving (moving) and delay due to congestion. The calculated evacuation time is estimated from the evacuation trip origin to the study area gateways identified on **Figure 2**.

Note: The calculated evacuation time does not account for unexpected complications or incidents on the roadways during the evacuation.

It should be noted that some phases may not occur. This can result from a variety of events including failure of officials to identify the hazard, slow response in sending evacuation orders, damaged or non-functional communication networks, and/or a sufficiently high perceived threat of the hazard by residents that results in substantial self-evacuation. Additionally, research on California wildfire evacuations found that some people evacuated their home prior to receiving an evacuation order (Wong et al. 2020). This assessment assumes that El Dorado County officials and emergency response personnel will be able to send out informed evacuation orders in a timely manner. **Figure 11** shows typical evacuation phases.

Figure 11: Evacuation Phases

For the Self-Evacuation (Vulnerable Population), the analysis estimates the evacuation time beginning from the hazard being detected by the evacuees.

For the Ordered Evacuation, the analysis estimates the evacuation time beginning from the evacuation order being received by the evacuees. The evacuation time estimates do not account for the time it takes for a hazard to be identified or the amount of time it takes for the official release of an evacuation order to the public.

Modeling Results

The EVAC+ evacuation time estimates for the Self-Evacuation and Ordered Evacuation analysis are summarized below for the fire scenarios outlined in **Table 1** for the following analysis scenarios:

- Existing Conditions – Represents existing conditions (i.e., existing residents).
- Existing Conditions Plus Marble Valley Specific Plan – Represents existing conditions with buildout of the Marble Valley Specific Plan.
- Existing Conditions Plus Marble Valley & Lime Rock Valley Specific Plans – Represents existing conditions with buildout of both the Marble Valley and Lime Rock Valley Specific Plans.

Self-Evacuation (Vulnerable Population)

Self-Evacuation represents the evacuation of populations in the direct path of the fire where advanced notice is not available due to the fire's progression. These vulnerable populations are in the red areas (i.e., where the fire's progression is 60 minutes or less) shown in figures (**Figures 12 through 15**). As analyzed, evacuation is assumed to begin within 15 minutes of the fire's recognition. However, self-evacuation may

be a part of an Ordered Evacuation, representing an initial phase of the evacuation that occurs before the Sheriff issues an order to evacuate. Evacuation time is estimated from the evacuation trip origin to the closest safe location not in the direct path of the fire, which may be inside or outside the study area shown on **Figure 2**.

The analysis results for Self-Evacuation summarized in **Table 7** is supported by summary figures for each fire scenario. **Figures 12 through 15** present the following information for Fire Scenario 2, 4, 7, and 16, respectively, for each analysis scenario:

- Fire Progression – Shows the progression of the fire scenario in minutes for each analysis scenario.
- Vulnerable Areas – Identifies the areas/parcels in the red areas that have a fire progression of 60 minutes or less.
- Vulnerable Evacuees – Identifies the number of evacuees in vulnerable areas.
- Evacuation Vehicle Trips – Identifies the number of vulnerable evacuation trips for each analysis scenario.
- Maximum Total Time to Safety – Summarizes the total time required to move the vulnerable evacuees to the closest safe location not in the direct path of the fire, which may be inside or outside the study area shown on **Figure 2**.

As shown, the addition of the Project slows the progression of the fire event. Consequently, the vulnerable population in the existing community areas will decrease compared to existing conditions due to the fuels removed by the Project, fuels management activities, and the creation of fire breaks conducted around the Project perimeter. Under Fire Scenarios 2 and 4, all the existing community areas would be outside the vulnerable areas with the addition of both the Project and Lime Rock Valley Specific Plans.

For all fire scenarios, it would take less than 20 minutes to move all the vulnerable evacuees (i.e., existing or project evacuees) to a safe location, which is less than the 30 minute fire progression shown in **Figures 12 through 19**. The maximum total time to safety would decrease for existing vulnerable evacuees with the Project. This is due to the increased access to evacuation routes and the slowed progression of the fire created by the removal of fuels and vegetation and fuels management activities occurring with the Project, which creates additional safe areas for vulnerable evacuees to access.

(1) Evacuation vehicle trips include evacuation of the entire population (residents, students, employees, and visitors).

Ordered Evacuation

Ordered Evacuation represents the evacuation of the entire population (residents, students, employees, and visitors) in the evacuation area for an event with ample notice where emergency services are participating in the evacuation. As analyzed, the evacuation window is 3 hours (180 minutes) beginning from the Sheriff ordering the evacuation. Evacuation time is estimated from the evacuation trip origin to the study area gateways identified on **Figure 2**.

The analysis results for the Ordered Evacuation summarized in **Table 8** is supported by summary figures for each fire scenario. **Figures 16 through 19** present the following information for Fire Scenario 2, 4, 7, and 16, respectively, for both no project and with project scenarios:

- Fire Location and Wind Direction – Identifies the location and wind direction for the fire scenario.
- Evacuation Area – Identifies the evacuation area for the existing and project population.
- Evacuation Routes – Identifies the evacuation routes for each fire scenario, including available routes (i.e., 180 minutes or more), routes that are not available (i.e., less than 30 minutes), and routes that are partially available (i.e., more than 30 minutes but less than 180 minutes).
- Evacuation Vehicle Trips – Identifies the number of evacuation trips for existing and project populations.
- Evacuation Time Estimate – Summarizes the total time to evacuate the different populations for existing conditions and existing plus project conditions.

For all fire scenarios, it would take less than 200 minutes to evacuate the study area. For most fire scenarios, the addition of project evacuees would not increase the total time to evacuate existing residents. In most instances this is due to the increase in available evacuation routes (i.e., more routes) and an increase in the availability of evacuation routes (i.e., routes remain viable for evacuation longer), and the slower progression of the fire due to hardened site conditions and removal of wildland fuels (i.e., from development), and vegetation and fuels management implemented as part of the project.

Under Scenario 4, the addition of the Project would result in an increase of about 5 minutes in the total evacuation time for existing residents. Under this scenario, the fire location is on the south end of the Project, so the effect of the Project on the progression of the fire is limited because the Project does not remove fuels in the path of the fire. Consequently, the availability of EVA 2 is reduced to 150 minutes and the Northeast Access (i.e., Durock Road and the US 50/Cameron Park Drive interchange) is reduced to 90 minutes. This reduction in evacuation route availability results in longer travel time for some existing evacuees that must use more distant or more congested access routes. However, as outlined above in the Self-Evacuation analysis, the addition of the Project would decrease the time for existing vulnerable evacuees to move to safety. Consequently, the significance of the 5 minute increase in the total evacuation time, under Scenario 4, of all existing residents is reduced, since the addition of the Project

reduces the time it would take existing vulnerable evacuees to reach a safe location. Therefore, the increase in total evacuation time will not affect the ability to get to a safe location before direct exposure to the fire.

With the addition of the Project and the Lime Rock Valley Specific Plan, the total time to evacuate the existing evacuees would be like no project conditions. Again, this is due to the increased access to evacuation routes and the and the slower progression of the fire due to hardened site conditions and removal of wildland fuels (i.e., from development), and vegetation and fuels management implemented as part of the project.

The EVAC+⁴ results do not include potential unknown factors that could produce much longer travel times such as road closures due to stalled or inoperable vehicles or other blockages such as falling trees.

⁴ EVAC+ is a dynamic traffic assignment model, is built in TransCAD 8.0, sensitive to how demand flows in short periods of time affects the speed of travel on the roadway network and the resulting ability of individual roadway segments to accommodate that demand.

Cumulative Conditions

Fehr & Peers, in coordination with Firesafe Planning Solutions, emergency service providers, and fire agencies identified study area and evacuation routes for analysis, which are shown on **Figure 2**.

The evacuation assessment includes the following four development scenarios that were analyzed under existing conditions:

- No Project – Represents existing conditions (i.e., existing residents).
- Marble Valley Specific Plan – Represents existing conditions with buildout of the Marble Valley Specific Plan.
- Lime Rock Valley Specific Plan – Represents existing conditions with buildout of the Lime Rock Valley Specific Plan.
- Marble Valley & Lime Rock Valley Specific Plans – Represents existing conditions with buildout of both the Marble Valley and Lime Rock Valley Specific Plans.

The analysis results presented above for existing conditions are applicable to cumulative conditions, since the Project and proposed Lime Rock Specific Plan are the only significant development projects in the study area that would add substantial population and transportation facilities that may affect the evacuation routes that may be used by the existing communities in the study area.

East Ridge Village is an approved planned residential development between the Project (i.e., to the west) and the existing Blackstone community, east of Latrobe Road. As a planned development, East Ridge Village was not assumed in the evacuation time estimates presented above under existing conditions. In addition, East Ridge Village does not include any full access roadway connections to the Project or to the evacuation routes shown on **Figure 2**.

However, future development of East Ridge Village would affect the behavior of Fire Scenario 16 by reducing the progression of the fire event under cumulative conditions. **Figure 20** shows the progression of Fire Scenario 16 with the addition of the approved East Ridge Village development. As shown, East Ridge Village would substantially delay the progression of the fire event to the point where the fire would take 200 or more minutes to reach the Project and the fire would not burn through the project to existing communities to the east. slower progression of the fire due to hardened site conditions and removal of wildland fuels (i.e., from development), and vegetation and fuels management implemented as part of East Ridge Village.
